**GAY-LUSSAC, Joseph Louis**, a French chemist, born at St. Léonard, Limousin, Dec. 6, 1778, died in Paris, May 9, 1850. He was educated at the polytechnic school of Paris, then called *École centrale des travaux publics*, where he attracted the notice of Berthollet, and was employed by him for a short time in the laboratory of the government chemical works at Arcueil. He then returned to the polytechnic school as assistant professor. Observations made on balloon ascensions having led to the supposition that the magnetic force diminishes at great elevations above the surface of the earth, Gay-Lussac and Biot were commissioned by the institute to make experiments with reference to it. Two ascensions were made, the first, Aug. 23, 1804, by both, and the second, Sept. 15, by Gay-Lussac alone. In the latter he reached the extraordinary height of about 23,000 feet. These ascensions were the first made for exclusively scientific purposes. Their results were not conclusive, but interesting observations were made upon the decrement of temperature with the increase of elevation, and upon the uniformity in the composition of the atmosphere at all heights. On Oct. 1 of the same year Alexander von Humboldt and Gay-Lussac submitted to the French academy a joint paper upon the combination of gases, especially of oxygen and hydrogen, which attracted much attention and marks an era in the progress of chemical science. In 1805-'6 Gay-Lussac prosecuted in company with Humboldt scientific inquiries in France, Switzerland, Germany, and Italy. They were present at Vesuvius when there was an eruption and an earthquake. Their observations on terrestrial magnetism were published in the *Mémoires de la société d'Arcueil*. Gay-Lussac began in 1807 to investigate the expansion of the air and gases under increased temperatures, and established the law that when free from moisture they all dilate uniformly and to equal amounts for all equal increments of temperature, at least between zero and 100° C. He also showed that the gases combine in simple proportions of their volumes, and that the contraction sometimes experienced when sev-

eral of them are compounded is always an exact simple fraction, usually one half, one third, or one quarter of their joint bulk. Sir Humphry Davy having shown by means of the voltaic pile that potassium and sodium are not simple substances, as had previously been supposed, and having decomposed them by the same means, Gay-Lussac and Thénard obtained potassium and sodium in greater proportions even than they had been obtained by Davy himself. They also developed the compound character of boracic and fluoric acids, introduced new methods of analyzing organic substances by their combination with chlorate of potash, and elucidated the composition of many of these compounds. The results of their investigation were given in *Recherches physico-chimiques sur la pile, sur les alcools, &c.* (2 vols. 8vo, 1811). Gay-Lussac afterward made original researches of great value into the newly discovered elementary substances of iodine and cyanogen, into Prussian blue, chloric and hydrosulphuric acids, the theory of vapors, capillary attraction, and other subjects. Their results were published in the *Annales de chimie et de physique*, which he edited with Arago, and in other publications. In 1816 he invented the siphon barometer, since modified by Bunsen, by whose name it is best known. He also invented instruments for estimating the quantities of alcohol, chlorine, and alkali present in solutions, known severally as the alcoholometer, chlorometer, and alkalimeter. In 1832 he gave up the professorship at the Sorbonne, to which he had been appointed in 1809, and accepted that of general chemistry at the *jardin des plantes*. As an expounder of science he was distinguished for the clearness of his explanations. In 1831 he was chosen by the electors of his native town member of the chamber of deputies; and in 1839 he was made a peer of France.

**GAZA** (Arab. *Ghazze* or *Ghuzze*), a town of Syria, built partly on a steep hill, partly on the plain below, on the road leading to Egypt, between the Mediterranean and the desert; pop. about 15,000. It is situated about 3 m. from the sea, in the neighborhood of rich gardens, is not fortified, and consists partly of mud cottages, partly of ruinous stone buildings, which are occupied by the government and chief citizens. It is an important entrepot for the caravan traffic between Egypt and Syria. It has few relics of antiquity, and its only interesting edifice is a mosque which was originally a Christian church, founded, according to tradition, by the empress Helena.—The ancient city of Gaza, which some suppose to have stood nearer the sea, is known in the Bible as the most southern of the five confederate cities of the Philistines, and is often mentioned, as in the history of Samson. Its Hebrew name (*Azzah*) signifies "strong." On the conquest and division of Palestine by the Israelites, it was allotted to the tribe of Judah, which conquered it, but lost it again. It

shared in the wars of the Philistines with the Hebrews. Having become a possession of Persia, it was taken after an obstinate siege by Alexander the Great (332 B. C.); nearly all its inhabitants perished during the assault, and its commander Batia, at the conqueror's order, was dragged around the walls at the wheels of a chariot. After Alexander's death it was taken by Antigonus, and witnessed the defeat of Demetrius Poliorcetes by Ptolemy (312). After the restoration of Jewish independence by the Maccabees, it was several times assaulted, besieged, and taken by the princes of that house. The Romans ceded it to Herod the Great. Under Nero it was taken by the revolted Jews. Constantine restored its ancient splendor, made it a bishopric, and gave it the name of Constantia, with various privileges. These were abolished by Julian the Apostate, and restored by his Christian successors. The Arabs took it in 634, two years after the death of Mo-

Peripatetic, and devoted himself to translating from the works of Aristotle, Theophrastus, and Hippocrates into Latin, and from those of Cicero into Greek, and was also the author of a treatise on the Attic months, of a book on the origin of the Turks, and of a Greek grammar, which was published at Venice and often reprinted. After assisting at the council of Ferrero in 1439, he taught Greek at Ferrara by the invitation of the duke, and founded there an academy. In 1450 he was called by Pae Nicholas V. to Rome. He afterward lived at Naples under the patronage of Alfonso the Magnanimous, and at Rome under that of Cardinal Bessarion.

**GAZEL**, or *Ghazel*, a kind of lyric poem, consisting of from 5 to 17 stanzas of two lines each, all the second lines of which rhyme together. It is a favorite form in the poetry of the Turks and the Persians, and may be called the sonnet of the East. The last couplet al-

ways contains the real or assumed name of the author. The subjects treated in the gazel are either erotic and lecherous, or allegorical and mystical. Hafiz excels in this form of the lyric, and imitations of it have been made in German by Platen, Rückert, and others.

**GAZELLE**, the type of a group of the antelope family (see *ANTILOPE*) of beautiful form, small size, and graceful carriage. Both sexes are provided with horns, nearly over the orbits, annulated and striated, nearly vertical, and bending outward and at the top inward in a

Gaza.

hammered. The crusaders captured it in 1100, and from them it was wrested by Saladin. In the 13th century it witnessed the defeats of the Christian armies by the Kharezmians and of the emir of Damascus by the Egyptians, and in 1516 that of the Mamelukes by the Turks. In 1771 it was seized by the revolted Ali Bey, and in 1799 by the French under Kléber.—Another Gaza (correctly, *Gazaen*) was in Media Atropatene, a summer residence of the Median kings. Ruins of it are seen between Miana and Tubriz.

**GAZI**, *Theodore*, one of those learned Greeks who contributed to the revival of letters in Italy, born in Thessalonica about 1400, died in Abruzzo in 1478. After the capture of his native town by the Turks in 1430 he fled to Italy, where he introduced a more exact knowledge than had before existed of the two principal philosophers of antiquity. He was a

lyrate form, and of a black color; the shape of the ancient lyre is said to have originated from using in its construction the horns and the frontal bone of antelopes, the strings being passed from a cross bar at their tips to a second fastened across the orbits; the bony core of the horn is solid. They have a small lachrymal sinus, inguinal pores, generally tufts upon the knees, a short dark-tufted tail, and two or four mammae; the darker color of the sides is separated from the white of the abdomen by a very dark band; the eyes are prominent, dark-colored, with a soft and gentle expression; the nose is ovine. They are gregarious, inhabiting the open and barren plains of northern Africa and western Asia, shy and difficult of approach, and extremely swift. The common gazelle, or Barbary antelope (*gazella dorcas*, H. Smith), the *gazal* of the Arabs, is generally supposed to be the *copiac* of *Ælian* and the *tassi* of the

**Scriptures.** It is a little less than the roebuck in size, with round, black, lyrated horns, about 13 in. long, with 12 or 13 bars, and sharp points turned forward; the general color is pale fulvous, extending down the front and outside of the limbs; the lips, nose, buttocks,

appears to be one or the other of the preceding species. Other gazelles are the m'hor of Mr. Bennett, the nanguer of F. Cuvier, and the ariel or cora, which are also supposed by many to be varieties of the *G. dorcas*. Sömmering's gazelle (*G. Sömmeringii*, Rüpp.) is a very beautiful and delicate creature, about

Common Gazelle (*Gazella dorcas*).

under parts, and inside of legs white; a rufous tint on the forehead, blackish in the middle, and white and black streaks on the nose; eyes large, black, and lustrous. The horns in the female are more slender, and the points are turned inward; the mammae are two. This species seems to be confined to the N. side of the Atlas mountains, Egypt, Abyssinia, Syria, Arabia, and S. Persia. They feed generally at dawn and at evening, approaching water, it is said, only once in 24 hours; they are hunted in various ways, and their flesh is excellent; they furnish food to great numbers of carnivorous animals. The kevel (*G. kevela*, H. Smith) is by some considered a mere variety of the common gazelle; it is about the same size, but the head is longer, the horns are

Sömmering's Gazelle (*Gazella Sömmeringii*).

2½ ft. high at the shoulder; the color above is a reddish-gray isabella color, the buttocks, lower parts, and inside of the limbs white, and the median line of the forehead to the nose brownish black; it inhabits N. E. Africa.

**GEAUGA**, a N. E. county of Ohio, drained by the sources of Cuyahoga, Grand, and Chagrin rivers; area, about 430 sq. m.; pop. in 1870, 14,190. It has an undulating surface, admirably adapted to pasturage. Sandstone and iron are abundant. The chief productions in 1870 were 64,815 bushels of wheat, 179,319 of Indian corn, 387,686 of oats, 185,781 of potatoes, 498,180 lbs. of flax, 377,941 of maple sugar, 105,811 of wool, 619,742 of butter, 458,834 of cheese, and 32,160 tons of hay. There were 4,622 horses, 18,674 milch cows, 7,267 other cattle, 19,818 sheep, and 4,844 swine; 6 manufactories of saddlery and harness, 12 of carriages and wagons, 8 of boxes, 27 of cheese, 4 flour mills, and 3 saw mills. Capital, Chardon.

**GÉBELIN**, *Court de*. See *COURT DE GÉBELIN*.

**GEBER**, *Abu Musa Jafar al-Sad*, founder of the school of Arabian chemists about the close of the 8th century, born in Thus, Persia, or, according to Abulfeda, in Harran, Mesopotamia. He is reckoned by Cardan as one of the twelve subtlest geniuses of the world, and his authority was unrivalled among the alchemists of the middle ages. His works, only fragments of which remain, contain the germs of the belief in the transmutation of metals, and in the universal elixir, which he thought to be a solution of gold. They also contain curious and useful details concerning the nature, fusion, purification, and malleability of metals. They have all been translated into Latin (Dantrie, 1682), and into English by Russell (London, 1678).

**GEBWEILER** (Fr. *Guebwiller*), a town of Germany, capital of a circle of Upper Alsace,

Kevel (*Gazella kevela*).

more robust and longer, the orbits larger, the eyes fuller, and the geographical distribution to the south of the Atlas; the habits and general disposition of the colors are the same as in the common gazelle. The corinna, found in central Africa and described by Adanson,

situated on the Lanch in a valley of the Vosges mountains, 15 m. S. W. of Colmar; pop. in 1871, 11,338. It has three gates, a fine promenade, two handsome churches, and many Swiss chalets and pleasant cottages on the slopes of Mount Gebweiler, the culminating point of the Vosges (4,700 ft.). There are manufactories of cloth, cotton goods, ribbons, chemical products, machinery, and other articles. Previous to the Franco-German war it belonged to the French department of Haut-Rhin.

**GECKO**, a name applied to a family of nocturnal lizards (*ascalabotæ* of Duméril and Bibron), numerous in species, living in warm climates, and presenting characters of form, structure, and habits which make the group as distinct as that of the crocodiles or chameleons. Their size is small; the head wide, flattened, covered with scales, with marginal scuta at each jaw; the neck short; the body depressed, stout, thickest in the middle, without crest on the back, generally covered with small imbricated scales and scattered tubercles, smallest on the back; the tail moderate; the feet five-toed, the thumb often very short, and the other fingers equal, flattened below and lobed at the end; the tongue is fleshy, short, slightly protractile, free and scarcely emarginate at the tip; the eyes very large, covered as in serpents by a transparent immovable lid, behind which these organs have free motion; the pupil vertical, and often linear as in nocturnal animals generally; the opening of the ear is distinct, and the tympanum depressed; there are no teeth on the palate, those of the jaws thin, entire, numerous, with cutting edges, and adhering to the internal margin; femoral pores occasionally present, but usually absent; besides the leaf-like expansion at the end of the toes, nails are generally present, capable of retraction, as in the cats, the latter favoring their progression in climbing on smooth surfaces. The tail is shorter than in ordinary lizards, and the flatness and width of the head give them somewhat the aspect of salamanders; the mouth is deeply cleft, and the widely expanded jaws may be kept open for a long time, the cavity of the mouth being shut off from the throat by the application of the base of the tongue to the posterior part of the palate; from the shortness of the robust legs, the abdomen touches the ground in walking. This reptile is mentioned by Aristotle, and the modern name gecko is derived from the sound made by some of the Indian species, resembling the click of the hostler urging on his horses, and was first given by Laurenti; this genus was the *ascalabotes* of Aristotle, the *stellio* of Pliny, and the *tarentola* of the ancient Italians. Their colors are generally gray or yellowish, but some have brighter tints which can be varied like those of the chameleon, probably by the same changes in the reflecting surface of the integuments; the sides of the body, limbs, and tail are sometimes fringed with membranes. In many species there is a line of pores along and under

the thighs, from which a fatty moisture distils: some species of a genus will have these, and others not, and sometimes one sex only will be destitute of them. The tail, as in salamanders, is ruptured with facility, and is reproduced readily, often in a deformed manner. Their food consists of larvæ and insects, which they pursue into their leafy retreats; the imbricated plates on the bottom of their feet, like those of the tree frog and flies, enable them to climb smooth walls and similar surfaces, and to adhere to them with the back downward; by means of their sharp, curved, retractile claws they can ascend trees and rough objects with ease and rapidity; from the quickness of their movements, their suddenly becoming motionless, and remaining so for a long time, and their resemblance to the colors of the substances on which they are placed, they are difficult to obtain, and not easy even to see; they hunt for food both by night and day; the same qualities which fit them for the pursuit of living prey enable them to escape their bird enemies. These reptiles are objects of horror and repugnance, from the erroneous idea that they emit a poison so powerful and subtle that a touch, a drop of their saliva, or a scratch, their nails, will produce leprosy and various diseases, often ending fatally. They like to approach human habitations, as they find in greatest abundance their food; their ill-shaped body, sooth or dull colors, large head, their eyes, rapid and silent motion, in houses, render them very disagreeable, but by no means dangerous inmates. In warm climates, they are very uncommon in Europe (two or three species), abundant in Asia, America, and the Pacific islands are well supplied with them. They have been divided into genera according to the form and structure of their toes; these generic characters in a family so unlike in its members are very unsatisfactory, and great and unnecessary multiplication of genera has been the result of the labors of various systematists. Duméril and Bibron, which that proposed by them, follows: 1. 1. with toes equal, all with finely imbricated plates; species having the feet with the toes unarmed, others with the thumb only and third fingers unarmed; if the unarmed feet the fingers are imbricated, or the thumb is imbricated. There are about 20 species, which have been made into genera by F. Mann, Kuhl, and others. 2. (Cuv.), with the toes widened into an oval disk striated beneath. 3. *Ptyodactylus* (Cuv.), with the thumb enlarged at the extremity into a fan, and the disk striated below like a fan, and

claws; destitute of femoral pores; four described species. 4. *Phyllodactylus* (Gray), with the terminal disk as in the last genus, except that two plates take the place of the fan-like strise; eight species. 5. *Sphaeriodactylus* (Cuv.), small species, with the toes ending in a single, simple, smooth cushion; nails absent, as well as femoral pores; three species. 6. *Gymnodactylus* (Spix), with toes not widened, but striated beneath; 12 species. 7. *Stenodactylus* (Fitz.), with simple toes, granulated below, and all provided with nails; with a single species.—As specimens of this animal the following may be mentioned: The wall gecko (*Pl. muralis*, Dum. and Bibr.; *Pl. facstanus*, Aldrov.) is 6 in. long, of a grayish color, the

Common Gecko (*Platydaetylus guttatus*).

upper part of the body and head rough; this species occurs all around the Mediterranean, and conceals itself in walls and stone heaps, delighting to cover itself with dirt and filth; it likes the heat of the sun, and, though beneficial in houses by destroying insects and vermin, is generally feared and persecuted, like the toad and other useful creatures. The common gecko (*Pl. guttatus*, Cuv.) of the continent of Asia and its archipelago is 11 in. long, of which the tail is about half; the general color is dark gray, with whitish spots. A common gecko in the walls of houses in the West

*Hemidactylus mabouia*.

Indies is the *H. mabouia* (Cuv.), about 5 in. long, of a grayish color marbled with brown, with the posterior half of the tail ringed with black. The house gecko (*Pt. Hameiquistii*, Dum. and Bibr.), found in Egypt, Arabia, and countries bordering on the eastern part of the

Mediterranean, is about 5½ in. long, of a reddish gray color, spotted with white and pale brown, and whitish below; it is common in the damp and gloomy parts of houses, and is called at Cairo "father of leprosy," from the belief that it communicates this disease to persons who partake of food over which this animal has walked, the poison being supposed to exude from the lobes of the toes. The truth is, that neither its bite nor any of its secretions are hurtful to man or beast; cats pursue it and eat it eagerly. The Egyptians are said to keep it from their kitchens by large quantities of garlic. The flat-tailed gecko (*G. phyllurus*, Dum. and Bibr.) has the tail flattened like a leaf, and the upper part of the body rough with spines; it is a native of Australia, and is about 9 in. long, dark gray, marbled with blackish above, and whitish beneath.

GED, William, a Scottish mechanic, the inventor of stereotyping, born in Edinburgh about 1690, died Oct. 19, 1749. He was originally a goldsmith in his native city, and is said to have first attempted stereotyping in 1725. In 1729 he entered into partnership with William Fenner, a London stationer, in order to carry his invention into regular practice, Fenner advancing the necessary capital on condition of receiving half the profits. Other partners subsequently joined the firm. In 1731 the company contracted with the university of Cambridge for the printing of Bibles and prayer books by stereotype, and invested a large sum of money in the enterprise; but when only two prayer books were finished the contract had to be surrendered, owing, as Ged alleged, to the malignant mismanagement of the pressmen, who were hostile to the innovation, and the disreputable conduct of some of his associates. In 1733 he returned to Edinburgh, where in 1736 he completed an edition of Sallust, which was not published till 1744, and was inaccurately executed. Ged died in poverty.

GEDDES, Alexander, a Scottish Roman Catholic ecclesiastic, born in Arradowl, Banffshire, Sept. 4, 1737, died in London, Feb. 20, 1802. He was educated at the Scotch college in Paris, where he distinguished himself as a theologian and linguist. In 1760 he was appointed pastor of a Catholic congregation at Auchinhalrig in his native county. In 1760 he removed to London with the intention of commencing a new translation of the Bible for the use of English Catholics; and under the patronage of Lord Petre, who allowed him £200 a year, and provided him with all the necessary authorities, he applied himself to his work. His original design was to make the Vulgate the basis of his translation, but he soon abandoned this idea, and substituted the Hebrew and Greek versions in its stead. The 1st and 2d volumes of this translation appeared in 1793 and 1793; the 3d, which was merely a commentary on the Pentateuch, in 1800; the rest of the work was never published. This translation is considered to have contributed in a considerable

degree to the advancement of Biblical criticism. The commentary was written in the spirit of the rationalistic school of Germany, and was favorably regarded by Paulus and Eichhorn, the principal writers of that school. Immediately after the publication of his commentary, the reading of his work was forbidden to the faithful, and the author was deposed from the priesthood. He was the author of several poems and translations, among which was an imitation of the satires of Horace, which had extraordinary success. A life of Geddes, with a catalogue of his works, was written by Dr. John Mason Good (1 vol. 8vo, London, 1803).

**GEEFS, Guillaume**, a Belgian sculptor, born in Antwerp, Sept. 10, 1806, died May 10, 1860. After completing his studies he went to Paris, where he spent some time in the studio of M. Ramey. Soon after returning to Belgium he obtained a commission from the Belgian government to execute a monument to the memory of the victims of the revolution of 1830. He also produced "Geneviève de Brabant," "Francesca da Rimini," "Fisherman's Daughter," "Infant St. John," &c., and executed a statue of Rubens, a colossal marble statue of King Leopold I. for the vestibule of the national palace, and a monumental statue of Charlemagne.—His brother **JOSEPH**, born in 1808, also a sculptor, distinguished by the same qualities, has executed among other works "Adonis departing for the Chase" and an equestrian statue of Leopold I. Their brother **ALOYS**, born about 1816, gave promise of great excellence as a sculptor, but died in 1841.

**GEELONG**, a city of Victoria, Australia, near the head of Corio bay or Geelong harbor, the W. arm of Port Phillip bay, 45 m. S. W. of Melbourne, with which it is connected by railway; pop. in 1871, 14,897. It is built on ground sloping to the bay; the streets are wide and well paved and drained, and the houses are mostly of brick and stone. The principal buildings are the hospital and benevolent asylum, the chamber of commerce, the mechanics' institute, the clock tower, the grammar school, the court house, the post office, several of the hotels, the churches, and the banks. There is an extensive botanical garden. The town is lighted with gas, and is supplied with water from the river Barwon. The surrounding country is beautiful, the soil fertile, and the climate healthy. There are four jetties in Corio bay, at which large ships can load and discharge, and the commerce in wool, tallow, gold dust, &c., is important. Three newspapers are published.—Geelong was first settled in 1837, and was incorporated in 1849. It first assumed importance after the discovery of gold at Ballarat, 48 m. N. W., in 1851, and for a time promised to become the principal seaport of southern Australia; but the construction of the railway from Melbourne to this point and thence to Ballarat diverted the produce of the interior to Melbourne.

**GEER, Karl de**, baron, a Swedish naturalist, born at Finspang, Feb. 10, 1720, died in Stock-

holm, March 8, 1778. He studied at Utrecht and Upsal, was a pupil of Linnæus, and published *Mémoires pour servir à l'histoire des insectes* (8 vols. 4to, Stockholm, 1752-75), containing descriptions of more than 1,500 species, accompanied with excellent illustrations. To this the *Genera et Species Insectorum* of Latreille (Leipsic, 1783) may be regarded as a supplement. De Geer also published several other zoölogical works. He inherited from an uncle a very large fortune, which he employed in benevolent and useful enterprises.

**GEERTS, Charles Henri**, a Belgian sculptor and wood carver, born in Antwerp in 1808, died in 1855. He was professor at the academy of Louvain. Among his principal works are "Christ sinking under the Weight of the Cross," in Leyden; a Madonna in the museum of Brussels; the "Mater Dolorosa" and "St. John" in Bristol. At the great exhibition of 1851 he gained a prize medal for his chief contribution, the "Coronation of the Virgin."

**GEESTERMÜNDE**, a seaport of Prussia, in the province of Hanover, at the confluence of the Geeste and Weser, separated by the Weser from Bremerhafen; pop. in 1871, 3,219. It was established by the government of Hanover as a rival of Bremerhafen, was made a free port in 1847, and in 1862 extensive harbor works were commenced. Since the annexation of it to Prussia, Geestermünde has become a station of a part of the German navy. The place possesses some advantages, which will probably render it an important port.

**GEEZ.** See **ETHIOPIA, LANGUAGE AND LITERATURE OF.**

**GEFFRARD, Fabre**, a mulatto soldier and general of Hayti, born at L'Anse-au-Loup, 1806. His father, Nicholas Geffrard, was a general of the war of independence, and one of the framers of the national constitution. He entered the army in 1821. In 1842 he rose to the rank of President Boyer in 1842 he rose to the rank and consideration, and became a general in the division in 1845, to which rank becoming emperor in 1849 added a great deal. Geffrard's popularity increased in proportion to the decline of that of his master. At the end of 1858 he led the revolution against him, proclaiming his deposition. While the emperor was in exile, he took his place with a considerable army. He succeeded in outwitting the emperor at Port-au-Prince Jan. 15, 1859, and drove him to Soulouque to Jamaica, and he was chosen as president, he was distinguished by acts of clemency: he declined to accept the title of emperor. Those who had committed the abuses now corrected by the revolution with the military of the revolution. Prophète, and he died in 1860. His life (Sept. 3), which was the result of the assassination of his daughter, who was married. The ministers and two of his sons were sentenced to death with their

others were executed, and a few were pardoned or imprisoned. In 1861 his popularity was impaired by what was denounced as his subserviency toward Spain on its taking possession of the Dominican republic; and intestine commotions being set on foot on various pretexts, outbreaks became henceforward habitual occurrences, which were suppressed and many of their leaders executed. In 1864 Salnave headed an insurrection in the N. part of Hayti, which had belonged to Dominica. This movement being put down and Salnave outlawed, he enlisted soldiers in the adjoining republic and proclaimed a provisional government of the Cape district in May, 1865. In November this was overthrown with the aid of the English, with whose rights it had interfered, and Salnave took refuge on board an American man-of-war. In July, 1866, he led a new outbreak at Gonaives, which was once more put down. To reconcile the people, who began to compare him with Soulouque, Gefrard abolished capital punishment for political offences; but the revolution continued and increased in strength till Salnave gained possession of the capital, March 18, 1867, and Gefrard was obliged to take refuge in Jamaica.

**GEFLE**, a seaport town of Sweden, capital of the län of Gefleborg, situated near the gulf of Bothnia and the mouth of the river of its name, 92 m. N. N. W. of Stockholm. It formerly contained a population of about 13,000, and was one of the handsomest towns in Sweden, but in 1869 it was almost totally destroyed by fire. The chief manufactures are tobacco, linen, sail cloth, cards, and leather. There are two ship yards.

**GEHENNA** (Heb. *Ge-Hinnom*, the vale of Hinnom), a valley adjacent to Jerusalem, on the south and southwest, also called Tophet, and often mentioned in Scripture in connection with the idolatrous rites of Moloch, which were there celebrated. From the abhorrence with which the Jews after the captivity regarded this worship, the valley was made the common sewer of the city, and a receptacle for all its refuse, which was there consumed by fire. In the New Testament the name is transferred by an easy metaphor to hell.

**GEIBEL**, Emanuel, a German poet, born in Lübeck, Oct. 18, 1815. He became associated in 1836 at Berlin with Chamisso, Gaudy, and Kugler, and was professor of æsthetics in the university of Munich from 1852 to 1868. Of his *Gedichte und Gedankenblätter*, the 9th edition appeared in 1868; of his *Neue Gedichte*, the 12th, and of his *Juniuslieder*, the 18th, in 1870; of his *Gedichte*, the 69th in 1871; and of his political poems, *Heroldsrufe*, the 4th in 1871. His principal dramatic poems are *Brunhild* (1857) and *Sophonisbe* (1868).

**GEIGER**, Abraham, a German rabbi, orientalist, and Biblical critic, born in Frankfort, May 24, 1810. He studied at the universities of Heidelberg and Bonn, gaining in the latter the prize for a dissertation on the Hebrew sources

of the Koran. In 1832 he became a rabbi at Wiesbaden, in 1838 at Breslau, in 1863 at Frankfurt, and in 1869 at Berlin, which position he still holds (1874). His efforts to effect reforms in Judaism have rendered him one of the most conspicuous Jewish theologians in Europe. From 1835 to 1847 he edited the *Zeitschrift für jüdische Theologie*, and in 1862 he started the *Jüdische Zeitschrift für Wissenschaft und Leben*, which he still continues. The most important of his writings are: *Lehr- und Lesebuch zur Sprache der Mischna* (Breslau, 1845); *Urschrift und Uebersetzungen der Bibel* (1857); and *Das Judenthum und seine Geschichte* (8 vols., 1865-'71; English translation of part I., New York, 1866).

**GEIJER**, Eric Gustaf, a Swedish historian and poet, born at Ransäter, Wernmland, Jan. 12, 1788, died in Upsal, April 28, 1847. At the age of 16 he was sent to the university of Upsal. He neglected to take his degree at the proper time, and consequently in 1803 was refused a tutorship in a distinguished family. This aroused his pride, and to restore his reputation he at once determined to contend for the next prize of the Swedish academy for excellence in composition. With very meagre authorities, and with scarcely paper enough for his manuscript, he wrote a eulogy upon the Swedish administrator Sten Sture, which obtained the first prize. He graduated master of arts in 1806, and after a short visit to England was appointed in 1810 lecturer on history at Upsal, and was a second time crowned by the academy for an essay on the question: "What advantages may be derived from the imagination in the moral education of man?" In 1811 he was one of twelve young men who founded the Gothic society, the object of which was to nurture a national spirit and national manners, and to derive the materials of literature, not from classical and foreign sources, but from the ancient traditions of the North. The new school was quickly divided into two parties, the Gothic and more moderate party, of which Geijer and Tegnér were the chiefs, and whose organ was the *Iduna*, and the Phosphorist party, so called from its organ the *Phosphoros*, of which Atterbom was the chief. In the *Iduna*, which appeared from 1811 to 1824, Geijer published his finest poems, as "The Viking," "The Last Scald," and "The Last Champion," which became immediately popular. His song of "The Charcoal Boy" is still a favorite throughout Sweden. In 1814-'15 he united with Afzelius in preparing a collection of Swedish popular ballads, and in 1817 was appointed professor of history at Upsal. He composed melodies for many of his own songs, and in 1824 published, in connection with Lindblad, *Musik för Sång och Pianoforte*. Liberal in politics and religion, he was twice offered a bishopric, which he declined, and twice represented the university of Upsal in the diet. His chief distinction is as the historian of Sweden. He was appointed with Fant

and Schröder to edit the collection of *Scriptores Rerum Suecicarum Medii Ævi* (2 vols., Stockholm, 1818-'25). His *Svea Rikes Håfder* ("Annals of Sweden," Upsal, 1825; translated into German, 1826) is a collection of dissertations on the early history and antiquities of the kingdom. His principal work is the *Svenska Folkets Historia*, ("History of the Swedish People," 3 vols., Örebro, 1832-'6; translated into German by Leffler, Hamburg, 1832-'6; into French by Lundblad, Paris, 1840; and into English by Turner, London, 1845), which extends only to the death of Queen Christina, but has been continued by Carlson. The work of Fryxell is also regarded as a supplement to it. At once a history of ideas, of manners, and of institutions, it is remarkable both for eloquence and learning, for its patriotic tone, synthetic views, and suggestive power. Among his minor publications are a "Sketch of the State of Sweden from Charles XII. to Gustavus III." (Upsal, 1839) and a "Life of Charles XIV. John," or Bernadotte (Upsal, 1844). A complete edition of his works has been published (12 vols., Stockholm, 1849-'55).

**GELA**, an ancient city of southern Sicily, on a river of the same name (now Fiume di Terranova), founded about 690 B. C. by a colony of Rhodians from Lindus and Cretans. It soon became flourishing, and was the parent of Agrigentum (now Girgenti), which afterward surpassed the mother city. The constitution of Gela was originally oligarchical, but was overthrown in 505 B. C. by Cleander, who was the first of its tyrants. His brother Hippocrates succeeded him, and extended its influence and power over the greater part of Sicily. His successor Gelon's transfer of the seat of his power and of a part of the inhabitants of Gela to Syracuse (485), his brother Hiero being made governor of the former, caused its decay; and its desolation was completed about 280 by Phintias, tyrant of Agrigentum, who removed its inhabitants to a new town, to which he gave his name. In the time of Augustus it was already in ruins, which are still visible in the vicinity of Terranova.

**GELATINE**, an azotized substance obtained from various parts of the animal body, such as the white fibrous tissue, the skin and serous membranes, and cartilage, by boiling in water. The substance as it exists in the body is probably not precisely the same as that obtained by boiling, although it cannot be said with certainty that the proportions of its chemical constituents have been changed. No precise formula of equivalents has been established, and it is therefore usual to write the composition of gelatine in percentage parts by weight. According to Mulder it consists, in 100 parts, of carbon 50.40, hydrogen 6.64, nitrogen 18.34, and oxygen and sulphur 24.62, of which about 0.7, according to Verdeil, is sulphur; but the presence of sulphur is disputed, and gelatine, although an azotized, is not a proteine substance. Frémy and Scherer make the percentage of

nitrogen rather less than that here given. The gelatine of commerce is prepared as follows: The skins of calves' heads and other thick pieces which are unfit for the manufacture of leather are first freed from hair and thoroughly cleaned of flesh and fat, and well washed. They are then reduced by cutting machinery to small pieces or to a pulp, cold water being allowed to run through the pieces during this operation in order to remove all impurities. The pieces of skin or pulp are differently treated by different manufacturers in order to obtain the solution most readily, some employing the mechanical force of rollers in conjunction with the application of a temperature varying from 230° to 250° F. When the solution is obtained it is clarified with some albuminous matter, as the white of eggs or ox blood, and after settling is drawn off upon shallow coolers, as plates of glass or slates. When partially dry, so that it can be cut into convenient shapes for handling, it is removed upon nets or placed in a vacuum drying apparatus to complete the process of desiccation. In the course of the preparation the substance is flavored with essences. Bones and ivory also are made to yield gelatine by subjecting them, when crushed, to water boiling at high temperatures in a digester, or to the action of steam gradually raised to the pressure of 21 pounds to the square inch, and thus kept for 24 hours. By this means their soluble portions are taken up, and the earthy matters, about 60 per cent. of the whole weight, are left behind, together with a soapy substance produced from the fat and lime of the bones. This residue is used for the manufacture of bone black, or the preparation of phosphorus, and is besides an excellent material for composts. The manufacture of gelatine has been largely carried on in France by first removing the earthy salts from bones by digesting them for many days in dilute hydrochloric acid, and afterward in boiling water.—For a long time gelatine was largely employed in the hospitals and pauper establishments of Paris, as a cheap and, as it was believed, very nutritive material for soup. Its value for this purpose was at last questioned, and the commission appointed to investigate its qualities reported unfavorably. It is, however, generally regarded as possessing nutritive properties, though in a less degree than fibrine and albumen; and even if insufficient itself to support life, its almost universal use in some form of food attests its importance as an article of diet. It also finds numerous other uses, as for the clarifying of liquors, in the manufacture of cements, as a chemical test for tannin, and in pharmacy for coating pills and forming pouches or capsules in which disagreeable medicines may be concealed and swallowed without disgust. It is also applied in the dressing of silk and other stuffs. It is made by the French into thin transparent sheets called *papier gâché*, which are used for copying drawings; and they also

prepare from it artificial flowers richly colored to imitate the natural specimena, or presenting the appearance, in their glittering and semi-transparent substance, of flowers wet with dew or drenched with rain. Another application of gelatine is for taking casts or forming moulds of objects presenting complicated forms, for retaining which plaster is not sufficiently adhesive. A series of casts in imitation of ivory were produced in this substance in 1844 by M. Franchi, for which the prize of the London society of arts was awarded in 1846. He afterward obtained gelatine casts from moulds of the same substance, the lines being perfectly retained in their original sharpness. He also took casts in gelatine from flat models, which he applied to cylindrical bodies, thus saving much expense in the carving or construction of intricate models.—Pure gelatine is colorless, transparent, inodorous, and insipid. It should be tested for smell by putting it in boiling water, as when dry the odor of glue may not be perceived. It softens and swells in cold water, but does not dissolve till heat is applied, a property which distinguishes it from fibrine and albumen. According to Bostock, one part of gelatine dissolved in 100 of water gelatinizes on cooling, but in 150 parts it remains liquid. When the solution is repeatedly warmed and cooled, especially if boiled, it loses its tendency to gelatinize, and becomes more and more soluble in cold water. Gelatine is soluble in all the dilute acids except tannic, in which respect it differs much from albumen. It is precipitated from aqueous solutions by excess of alcohol. Tannic acid is a very delicate test; when added to a solution of one part of gelatine in 5,000 parts of water, it will render it cloudy; when added to a strong solution, a dense curdy precipitate falls, which is the same substance as the basis of leather. Gelatine is rendered insoluble when mixed with chromic acid and exposed to the action of light. This property is applied in the manufacture of imitations of ivory, and in the reproduction of photographic prints, according to the invention of Woodbury and Albert.—Gelatine which is obtained from the sounds of fishes is called isinglass, and an impure variety is known as glue. (See GLUE, and ISINGLASS.)

**GELDERLAND**, or **Guelderland**, a province of Holland, bounded N. W. by the Zuyder Zee, S. E. by Prussia, and on the other sides by the provinces of Overijssel, Utrecht, South Holland, and North Brabant; area, 1,964 sq. m.; pop. in 1870, 432,693. Its surface is more hilly than that of most of the Netherlands; its climate is mild, but its soil, except in the river valleys, is poor. The principal streams are the Maas (separating it from North Brabant), Waal, Rhine, and Yssel, on the banks of which fruit, grain, hops, potatoes, and tobacco are cultivated with considerable success, while the more sterile districts have recently been planted with timber, or are used for cattle raising. Brewing, distilling, and the manufacture of paper, linen, tiles,

and leather, are important branches of industry, and there is also an extensive transit trade. There are iron mines in the canton of Zutphen. The herring fishery is actively prosecuted on the Zuyder Zee. Arnhem, the capital, Nimeguen, Zutphen, and Harderwyk are the chief towns.—Gelderland was made a county in 1079 by the emperor Henry IV., and a duchy in 1389 by Louis the Bavarian. It was governed by dukes of its own, who resided at its present capital, till 1528, when it passed into the hands of Charles V. It joined the union of Utrecht in 1579. In 1794 it was taken by the French, who held it till 1814, when it became a part of the Netherlands. A portion of upper Gelderland (area, about 450 sq. m.), including its capital Geldern, was added to Prussia by the peace of Utrecht (1713), and now forms part of the circle of Geldern in the district of Düsseldorf.

**GELDERN**, a town of Prussia, in the province of the Rhine, on the Niers, 28 m. N. W. of Düsseldorf; pop. in 1871, 5,096. It has a Catholic and a Protestant church, two convents, manufactures of cloth, stockings, hats, woollen, silk, and linen goods, and a considerable trade in grain. The town was built in 1097, and was till 1348 the residence of the counts and dukes of Geldern. (See **GELDERLAND**.) Its fortifications were razed by Frederick the Great in 1764.

**GELL**, Sir **William**, an English scholar, born at Hopton, Derbyshire, in 1777, died in Naples, Feb. 4, 1836. He graduated at Cambridge in 1798, and was sent on a secret mission to the Ionian Islands. In 1814 he accompanied the princess of Wales abroad as one of her chamberlains, and was one of the witnesses at her trial, after she had become queen. He subsequently returned to Italy, where he sojourned till his death. He was a voluminous writer on classical antiquities. His principal works are: "The Topography of Troy and its Vicinity" (fol., 1804); "Itinerary of Greece, with a Commentary on Pausanias and Strabo" (4to, 1810); and "Pompeiana, or Observations upon the Topography, Edifices, and Ornaments of Pompeii" (with J. P. Gandy, 8vo, 1817-'19; 3d ed., 1852). Of the last, a continuation in 2 vols. 8vo was published in 1832.

**GELLERT**, **Christian Friedrich**, a German poet and moralist, born in Hainichen, Saxony, July 4, 1715, died in Leipsic, Dec. 13, 1769. He was one of the early promoters of the great literary movement which produced Schiller and Goethe. The latter in his youth was one of his disciples, but judged his ethical system to be of an effeminate tendency. He published fables and poetical tales, which are still popular, letters, sacred hymns and odes, and a romance entitled "The Swedish Countess." He was professor of philosophy in the university of Leipsic.

**GELLIUS**, **Annia**, a Roman grammarian, who flourished about the middle of the 2d century A. D., supposed to have been born in Rome. He studied rhetoric there, and philosophy at

tries, particularly Hindostan, Pegu, and Ceylon, have been famous from the remotest periods for their rich gems; and in modern times Brazil, Peru, and south Africa have rivalled them in these productions.—**GEM ENGRAVING**, known also as the glyptic art (Gr. γλυπτεν, to engrave), was skilfully practised in very remote times. In Exodus xxviii. 17–20, the following stones are designated as those upon which were engraved the names of the 12 children of Israel: sardius, topaz, carbuncle, emerald, sapphire, diamond, ligure, agate, amethyst, beryl, onyx, and jasper. At this early period, as we learn from verse 11 of the same chapter, engraving of signets, and upon the hardest stones, was practised. The Israelites, it is believed, acquired the art from the Egyptians, who are known to have made use of the lapidary's wheel and emery powder, and are supposed to have been acquainted with the diamond and the method of engraving other hard stones by means of it. The Assyrians and Babylonians were very skilful in engraving on gema, many of which have been found in the ruins of their cities. Many of their seals are most delicately and minutely ornamented with various sacred devices and with the forms of animals. The Greeks adopted the art, and practised it with the greatest zeal and success. Their works of the time of Alexander the Great are still the most perfect specimens. The most distinguished among their earlier artists was Pyrgoteles, who alone was permitted to engrave the head of Alexander, as Apelles only was allowed to paint his portrait, and Lysippus to cast his image in bronze. During the reign of Augustus in Rome, Dioscurides from Æolia in Asia Minor attained the highest eminence. His head of Io is regarded by some as the finest engraved gem in existence, and others almost equally beautiful are two busts of Augustus, a head of Demosthenes on an amethyst, and various mythological representations. Several of the most skilful artists of Greece established themselves at Rome under the emperors. With the empire the art declined, and though the mechanical execution was not lost, no productions of genius appeared till the 15th century. At this time it became fashionable to make collections of antique gems, and among others Lorenzo de' Medici was especially interested in this object and in encouraging artists to imitate the finest productions, in which they attained great success. The same taste soon spread to France, Germany, and England; and in all civilized countries the art has since been held in high estimation. As applied to the hardest gems, as the diamond, ruby, sapphire, and topaz, it is no doubt carried to a higher degree of perfection than was attained in ancient times, for among the antique engraved gems preserved there are few if any of this class. Engraved gems are for the most part readily referred by connoisseurs to their true period, country, and sometimes to the artist himself. Each had his own cipher, which is

commonly found upon the gem, though this is in modern times imitated, together with the peculiar style of the ancient artists and their complete work, in great perfection. Specimens of Egyptian art are recognized by the representations of the peculiar favorite animals and divinities of this people, accompanied with their hieroglyphics. Their gems were engraved almost exclusively in intaglio, and they were of the form designated as *scarabæi*, from the upper surface of the stone, always of the oval form, being cut to represent the beetle. The Etruscans also adopted this form, but their devices more resemble those of the earliest Greek workmanship. Their specimens are distinguished by low relief, a granular border surrounding the engraving, stiffness in the figures, peculiar style of letters and writing, wings given to the deities which the Greeks represent without wings, and names generally attached to the figures. The Greeks also practised chiefly in intaglio, and some of their finest works are in chalcedony and carnelian. The highly famed Dionysiac bull of Hyllus, an artist supposed to have lived before the age of Augustus, is upon chalcedony; and a celebrated specimen in carnelian is the beautiful seal which once belonged to Michel Angelo, and was afterward preserved in the national library at Paris. The engraving represents a vintage, but the design has been referred in various learned dissertations to a number of different objects, some of mythological character. Many impressions and copies have been taken of this famous specimen. The engraved gems of the first 15 centuries A. D., excepting the imitations of antique works, generally have designs from Scriptural subjects—images of Christ and of the Virgin Mary, representations of the Good Shepherd, and often a fish, symbolical of the Saviour, from the letters in its Greek name, ἰχθῆς, being the initial letters in the appellation Ἰησοῦς Χριστὸς Θεοῦ Υἱὸς Σωτῆρ. Some terms employed to designate certain styles of antique gems may be properly noticed here before speaking of the art in modern times. Stones convex on one side are said to be *en cabochon*; *chimæra* are those with representations of imaginary beings made up of portions taken from different animals; *grylli* are those with hideous heads, said to be so called from an Athenian named Gryllus, who was extraordinarily ugly; *conjugata*, or joined, are those with heads represented together upon the same profile, called opposite when they face each other. Engraving was practised both in intaglio and in rilievo, and the two styles were sometimes combined in the same specimen. Stones having differently colored layers, like the onyx, were especially adapted for the rilievo style, for an account of which see **CAMEO**.—In modern times the finest gem engravers are found among the Italian artists of the 18th century, and chiefly those of Florence. Some of their works are hardly inferior to those of the most famous Grecian artists. Flaviano Sirletti of Florence, who died in 1787, was especially distinguished

for his copies of ancient gems and exact imitations of the ancient letters. The Costanzis and many others also attained great repute; and in the present century are some whose productions, as those particularly of Signor Rega of Naples, rank with the famous antique gems. Among the Germans, Daniel Engelhard of Nuremberg, a friend of Albert Dürer, was celebrated for his skill in engraving crests and arms. He died in 1552. The works of the Pichlers, father and son, who came from Tyrol, are of the highest merit, especially those of the father. The son was much in Italy, and is often spoken of as an Italian. The celebrated Poniatowski collection of antique gems has recently been credited to the elder Pichler. Natter of Swabia, who died in 1763, was not only a workman of the most delicate skill and refined taste, but a student and author also, and published in 1754 a treatise specially devoted to his art: *Traité de la méthode antique de graver en pierres fines comparée avec la méthode moderne*. From this work it appears that the ancients employed the same sort of tools and the same methods as those in use at the present day. The modern practice is described by Holtzapffel in vol. iii. of his "Mechanical Manipulation."—The apparatus employed in engraving consists of a foot lathe attached to a small table, upon which is fixed a little pillar for holding the horizontal pulley, which is the receptacle for the cutting tool. This part of the apparatus is called the mill. The tools are soft iron wire spindles carefully annealed and nicely fitted to the hollow axis of the pulley. Only one is used at a time. When set in its place it projects through the bearings of the pulley, one end extending horizontally on the right-hand side of the operator, who sits at his work in front of the table. This extremity of each tool is fashioned for its special work. Most of them terminate in a small disk, the edge of which, as it rotates rapidly, cuts lines in the stone held up against it, the tool being fed with diamond dust and oil. The larger sized disks are only about a quarter of an inch in diameter, and from this they are made of decreasing sizes down to  $\frac{1}{16}$  of an inch, when the disk can scarcely be distinguished by the eye from the stem. They are also variously shaped for special kinds of cutting. The stone intended to be engraved is usually shaped by the lapidary, and is sometimes set by the jeweller before it is engraved. If not set, the engraver secures it to a wooden handle by the cement known as the lapidary's; or if set, he secures it in a notch in a piece of cork. The polish is removed by roughening the face with a suitable cutting powder, as the tools work better upon a rough surface, and the outline of the design, which is next marked with a brass point, is the more conspicuous. The area thus enclosed is then sunk by the tools to a suitable depth; and within this the details of the design are successively introduced and excavated. For the parallel lines, called color lines, a thicker disk with two cutting edges is

employed, its form being that of a little pulley; the two edges are just as far apart as the lines they are intended to cut, and as one pair is cut the stone is moved so as to bring the outer edge of the disk into the groove marked by the other edge, and thus the work goes on step by step over the surface to be thus "colored." The plan must be perfectly understood by the artist at the commencement of his work, and as it goes on he watches the effect produced with the aid of a magnifying glass conveniently attached to a stand over the tool, and occasionally takes a proof of his work in wax. After the stone is engraved the polish is restored to the flat surface by a pewter polishing disk or lap fed with rotten stone and water. The engraved portions are polished with great care, first by using in the mill copper tools charged with diamond powder; this buries itself more deeply in the copper than in the iron tools, and a smoother surface is thus obtained. Boxwood tools charged with still finer diamond powder are next used, and after these copper tools charged with rotten stone and water. The harder gems, excepting the diamond, which engraved with the greatest difficulty, are adapted for this process than those of quality. The latter are liable to hold diamond powder and cause it to wear out tools; they do not when finished present smooth and highly polished surfaces as harder stones. The amethyst is softer a stone as can be cut very easily. The emerald, garnet, and bloodstone are of close texture and admit of excellent work; the ruby is hard but small pieces are apt to flake off. The sapphire is firm and close; it cuts slowly, but sends beautifully smooth surfaces.—**ARTIFICIAL GEMS.** The great value attached to natural stones led at an early period to attempts to imitate them. The Egyptians possessed the art of coloring glass, and the mixtures they produced excellent. The most beautiful gems, so that, as it was difficult to distinguish the artificial from the real. Their artificial emeralds, hyacinths are spoken of by various authors. Some of the first named was of gigantic size that they were used in the construction of statues, as of that of the Egyptian labyrinth, 18½ ft. high, presented by the king of Egypt. An obelisk in the temple of Luxor and 6 ft. broad was composed of emeralds. These were very extraordinary productions if made only of pieces of colored glass. Seneca also makes mention of glass who manufactured them. Pliny the Elder states that in the time of Augustus at Rome are pieces of glass which were once used in the construction of the Victoriae are of faultless execution. The discovery of the preparation of oxide of tin, called ponce, is

the means of giving a ruby-red color to glass, and artificial rubies were then first made, especially by one John Kunkel, afterward Löwenstiern, inspector in 1679 of the glass houses in Potsdam. In modern times the art has been wonderfully perfected by the French, chiefly through the genius of M. Donault-Wieland. A glass called strass, of great lustre and perfectly transparent, of which the ingredients are given in the article GLASS, is prepared as the basis of the composition. It resembles the diamond in high refractive power as in its other qualities, except hardness. That it may be free from color its ingredients must be absolutely pure; and care must be exercised in selecting crucibles least likely to impart color to the fused mixture. Artificial diamonds are made from pure strass, which is cut directly into brilliants and roses, without the addition of other matter. Other gems are imitated by melting and mixing it with substances having a metallic base, generally oxides, which communicate the various colors.—The researches and experiments of M. Ebelmen are of a higher order of art. He conceived the idea in 1847 of forming various mixtures with some ingredients volatile at very high heat. By the dispersion of these in the furnace the other ingredients should crystallize, as substances held in solution in liquids crystallize when these are evaporated. He thus proposed to produce the ruby, corundum or sapphire, and other precious stones. The volatile solvents or fluxes he employed were principally boracic acid and borax. The spinelle ruby, among the first minerals he imitated, was obtained by mixing together 30 parts of magnesia, 25 of alumina, 1 of chlorate of potash, and 85 of boracic acid, and subjecting 500 grammes (7.716 grains) of the compound to high temperature in the muffle of a furnace for eight days. The crystals measured 0.197 inch on a side. Chrysoberyl was produced in crystals with faces of 0.24 inch, perfectly transparent, and scratching topaz from a mixture of alumina 12 grammes, glucine 3.5, carbonate of lime 10, and fused boracic acid 14 grammes. The object of the lime was to form a fusible borate for holding the other ingredients in a condition favorable for crystallization. Chrysolite in well defined crystals resulted from silica 4.5, magnesia 6.15, and boracic acid 6. Transparent crystals of pure alumina, which are sapphire or corundum, and which presented the same hardness and specific gravity with this mineral, were a product of alumina thus fused with 3 or 4 parts of borax, or of 10 parts of alumina with 4 of silica and 16 of borax. M. Ebelmen employed also as fluxes the salts of phosphorus and the carbonates of potash and of soda, all which are volatile at high temperatures, and by means of these solvents reproduced many other minerals, as he announced to the academy in 1851. His death shortly after terminated his interesting researches; but they have been successfully continued by Deville,

Elsner, Manross, and others, and numerous artificial minerals have been prepared.—The great establishment of M. Bourguignon in Paris was at one time the most famous manufactory of artificial gems in the world. About 100 workmen, besides many women and girls, were constantly employed in preparing and fusing the mixtures, cutting and polishing the stones, and lining the imitation pearls with fish scales and wax. The sand used to furnish the silica is from the forest of Fontainebleau; and its quality is so highly esteemed that much is exported for similar use elsewhere. The gems are such perfect imitations that they can be distinguished from genuine stones only by the closest scrutiny of those experienced in such matters. The great hardness of the natural stones it is found most difficult to imitate, and there is a want of permanency in the qualities of most of the imitations, which at last causes their true character to appear.—See "A Popular Treatise on Gems," by Dr. L. Feuchtwanger (New York, 1859; revised ed., 1867); "The Natural History of Gems," by C. W. King (London, 1867); "Diamonds and Precious Stones," by Harry Emanuel (London, 1867); and "Diamonds and Precious Stones," translated from the French of Louis Dieulafoy by F. Sanford (New York, 1874).

**GEMINI** (the twins), the third constellation in the zodiac, so named from its two brightest stars, to which the names Castor and Pollux are given, and which are about midway between Aldebaran and Regulus.

**GEMISTUS**, George, surnamed **PLERNO**, a scholar and philosopher of the 15th century, born in Constantinople, and said to have lived to the age of 100. He held a high position at the court of the Palæologi, and at the council of Florence in 1439 opposed the union of the churches of the East and the West. Subsequently banished from his country, he found an asylum in Italy, and declared himself in favor of the Latins. While the philosophy of Aristotle was still reigning, he became an enthusiastic votary of the Platonic theories in metaphysics and natural theology, and being admitted to the circle of the Medici, prompted Cosmo to found his celebrated Platonic academy. His treatise in praise of Platonism inaugurated the long quarrel between the disciples of the two great masters of antiquity, which produced a profound study of their systems. Gemistus, however, mingled with the Platonic philosophy the notions of the later Alexandrian school and of the spurious writings attributed to Zoroaster and Hermes, and revived in the West that eclecticism, half Christian and half pagan, half oriental and half Greek, which flourished during the decline of the Greek philosophy at Alexandria.

**GEMÜNDER**, George, an American violin maker, born at Ingelfingen, Würtemberg, April 13, 1816. He was a pupil of Baptiste Vieux in Paris, and removed to the United States in 1847, establishing himself in Boston,

Mass. In 1851 his violins obtained the prize medal of the world's fair in London. In 1852 he removed to New York, where he has since lived. Vuillaume and other makers of violins in Europe adopted the practice of giving a pseudo-antiquity to their wood by a chemical process, in order to gain for their instruments a desirable quality of tone; but wood thus treated soon loses its resonance, and after a time the instruments become worthless. Gemünder, rejecting this method, has succeeded with natural wood in producing violins which fulfil every requirement, and in respect of volume, power, equality, and quickness of tone, are fully equal to the work of the best old masters. In the model and finish of his instruments, and especially in the varnish, he is exceedingly successful. He reproduces faithfully the distinctive characteristics of the old Italian violins, so that his instruments are often taken for genuine productions of Cremona. One called the Kaiser violin, finished in 1873 and exhibited in the great exposition at Vienna, was pronounced an Italian violin of the classic period, because it was believed impossible to produce so fine a tune in a new instrument.

**GENDRIN, Auguste Nicolas**, a French physician, born at Châteaudun, Dec. 6, 1796. He received a doctor's diploma in 1821, and published on this occasion *Du traitement de la blennorrhagie*, relating to his new method of injecting opium. His *Recherches sur la nature et sur les causes prochaines des fièvres* (2 vols., 1823), and his *Histoire anatomique des inflammations* (2 vols., 1826), which latter has been translated into German, won academical prizes, as did some of his subsequent writings, the most renowned being his *Traité philosophique de médecine pratique* (3 vols., 1838-'41). After having been attached to various hospitals, he was from 1836 to 1866 the principal physician of La Pitié. During the June insurrection of 1832 he incurred odium for having, as alleged, reported to the authorities political offenders on whom he had happened to attend professionally; and his *Mémoire médico-légal*, showing that the prince of Condé did not die by his own hands in 1830, but by those of assassins, also gave rise to unfavorable comments, which he endeavored in vain to combat.

**GENDRON, Auguste**, a French painter, born in Paris in 1818. He studied under Delaroche and in Italy, and became famous (1844-'6) by his picture representing *Les willis*, or maidens resuscitated from their graves according to a Bohemian legend, and dancing during a whole night. His "Dante commented upon by Boccaccio" (1844), his "Sylphs" (1852), "Titania" (1853), and many other works, have since been exhibited. He excels in historical, fantastic, and fairy delineations, and has also painted on porcelain for the manufactory at Sèvres, and remarkable decorations for the palais d'Orsay.

**GENELLI, Bonaventura**, a German painter, born in Berlin about 1798, died in Weimar,

Nov. 13, 1868. He studied under his father, who was a landscape painter, and at the academy in Berlin, and during ten years in Italy, chiefly in Rome. He was subsequently employed in classical decorations at Leipzig till 1836, when he removed to Munich. In 1839 he was invited to Weimar by the grand duke, and spent there the rest of his life. His most famous works are "Lot's Entry into Zoar," and aquarels illustrating *Æsop*, *Homer*, *Apollon*, *Sappho*, *Dante*, the life of a witch, and the life of a rake. His later works are chiefly paintings relating to mythological and classical subjects, upon which he brought to bear a glowing imagination and great ideality. The publication of some of his later paintings was begun in 1870 in a work entitled *Satura*.—His brother **HANS CHRISTIAN**, born in Berlin, Dec. 8, 1823, has published several works relating to the fine arts, and excels as a draughtsman and architect. His son **CAMILLO**, who died in 1867, gave promise of being a good painter; and his daughter **GABRIELE** is a popular actress.

**GENESEE**, a river of western New York, rises in Potter co., Pa., within a few yards of the head waters of the Alleghany and the north branch of the Susquehanna, flows N. W. and N. E. through Alleghany, Wyoming, Livingston, and Monroe counties, N. Y., and falls into Lake Ontario 7 m. N. of Rochester. Its length is about 145 m. It is navigable from Lake Ontario to the N. line of Rochester. The mouth, protected by two fine piers, forms a good harbor, which gives rise to the village of Charlotte, on the W. side. The river abounds in beautiful scenery, especially in rapids. In Livingston co., near Potsdam, there are three falls within a distance of two miles, which are respectively 60, 90, and 120 ft. high; and for several miles below the first the stream flows between perpendicular cliffs 400 ft. high. At the S. line of Livingston co. it commences a series of rapids, which in the centre of the city in a sheer fall of 100 ft., called Genesee falls. This was the scene of Sam Patch's last leap. Six miles from the mouth of the river is a large lake, called Seneca, by which the stream receives its name. The Genesee is tapped above the falls to feed the Erie canal, which at Rochester it crosses by a fine limestone aqueduct of each of 50 ft. span. The canal commencing at Rochester and flowing N. W. of the river for a course of 10 miles, empties into it at Mt. Seneca.

The Erie railway has a station at this place, 800 ft. long and 204 ft. wide.

**GENESEE**, L. A. W. Co., drained by Tonawanda cr., 1,200 sq. m.; pop. in 1870, 21,000. The soil is almost level, and is a very sandy soil, and pasturage. The places, and iron, are obtained. The

New York Central railroad, the Batavia and Attica branch, the Canandaigua, Batavia, and Tonawanda branch, and the Erie railway. The chief productions in 1870 were 722,874 bushels of wheat, 428,710 of Indian corn, 509,690 of oats, 380,406 of barley, 21,447 of buckwheat, 275,717 of potatoes, 42,891 of peas and beans, 883,721 lbs. of butter, 461,337 of wool, 143,208 of hops, and 60,144 tons of hay. There were 10,411 horses, 10,485 milch cows, 7,796 other cattle, 73,884 sheep, and 8,496 swine; 5 manufactories of agricultural implements, 3 of brooms, 30 of carriages and wagons, 3 of cheese, 9 of clothing, 18 of barrels and casks, 1 of malt, 14 of saddlery and harness, 8 of tin, copper, and sheet-iron ware, 13 flour mills, 1 planing mill, 9 saw mills, 4 tanneries, and 3 currying establishments. Capital, Batavia. II. A S. E. county of the S. peninsula of Michigan, drained by Flint and Shiawassee rivers; area, 500 sq. m.; pop. in 1870, 33,900. It is intersected by the Flint and Père Marquette, the Detroit and Milwaukee, and the Port Huron and Lake Michigan railroads. Its surface is undulating, covered with extensive oak openings in the S. part, and densely wooded with pine and other timber in the N. The chief productions in 1870 were 553,133 bushels of wheat, 326,637 of Indian corn, 410,561 of oats, 288,829 of potatoes, 910,876 lbs. of butter, 375,877 of wool, and 49,041 tons of hay. There were 7,486 horses, 8,850 milch cows, 11,300 other cattle, 79,306 sheep, and 9,818 swine; 13 manufactories of agricultural implements, 4 of boots and shoes, 8 of bricks, 31 of carriages, 9 of barrels and casks, 18 of furniture, 12 of iron castings, 18 of saddlery and harness, 8 of sashes, doors, and blinds, 11 of tin, copper, and sheet iron, 8 of woollen goods, 18 flour mills, 5 breweries, 3 planing mills, and 50 saw mills. Capital, Flint.

**GENESIS**, the name of the first book in the Bible, denoting in Greek "the generation," i. e., the account of the generation or production of all things. In Hebrew Bibles it is called *Bereshith*, signifying "in the beginning," because it commences with that word. By some Jewish writers it is also called *Sepher yetzirah*, the book of creation. Its history goes back to the very earliest ages of the human race, and covers a period of upward of 2,300 years; giving an account of the creation, the fall of man, the religion, arts, settlements, genealogies, corruption, and destruction of the antediluvian world; of the re-peopleing and division of the earth, the dispersion of its inhabitants, the calling of Abraham, and the rise and progress of the Hebrew nation, to the death of Joseph.—For all questions relating to the authorship and authenticity of the book, see **PENTATEUCH**.

**GENET** (in this country commonly written **GENET**). **Edmond Charles**, a French diplomatist, born in Versailles, Jan. 8, 1765, died at Schodack, Rensselaer co., N. Y., July 14, 1834. Although his father was attached to the court and his

sister, Mme. Campan, was in the service of Marie Antoinette, he made himself known by his republican opinions. In April, 1789, he was appointed chargé d'affaires to the court of St. Petersburg, where his situation soon became uncomfortable; in 1791 he was informed by Count Ostermann, minister of Catharine II. that he would better not appear again at the court; and in July, 1792, he was formally dismissed. On his return to France he was appointed ambassador to Holland; but before going thither he received (December, 1792) his nomination as minister to the United States. He arrived in April, 1793, at Charleston, S. C., where he was cordially welcomed. On May 20 he had a triumphant reception in Philadelphia; the citizens presented him with an address congratulating France upon obtaining the freedom she had helped the United States to secure. Encouraged by these demonstrations of popular feeling, Genet thought he could easily persuade the American people to embark in the cause of France, notwithstanding the proclamation of neutrality recently issued by President Washington. He openly maintained that the United States were in duty bound to side with France against England, and bitterly denounced the American government for want of sympathy toward the French republic. He even fitted out privateers from Charleston, to cruise against the vessels of nations then at peace with the United States, and to project hostile expeditions against Florida and Louisiana, then colonies of Spain. In consequence of these imprudent measures Washington demanded and obtained his recall. Genet decided not to return to France, settled in the state of New York, was naturalized, and married a daughter of George Clinton.

**GENET** (*genetta*, Cuv.), a digitigrade carnivorous mammal of the family *citellidae*, inhabiting Africa, and occasionally found in southern

Common Genet (*Genetta vulgaris*).

Europe. The dentition and structural characters are the same as in the civet, the principal difference being that the anal pouch which contains the glands secreting the odorous substance is much less developed and prominent in the genet than in the civet. The common

genet of Barbary (*Civerra genetia*, Linn.; *G. culgaria*, Cuv.) is ashly gray, with blackish spots; the tail is nearly as long as the body, with long hair and 10 or 11 dark and light rings; the length of the body is about a foot and the tail about the same, and the height 5

Pale Genet (*Genetta Senegalensis*).

in. It is only semi-carnivorous, and will live in captivity wholly on vegetable food. The claws are sharp, semi-retractile, and well adapted for climbing; the anal secretion has a musky odor; as in other nocturnal animals, the pupil is vertical. The habits of the genet are like those of the weasel tribe; it is easily tamed, and is sometimes employed to catch rats and mice in houses; the period of gestation in captivity is about four months. The pale genet (*G. Senegalensis*, Fischer), or fossane, resembles the former species, and is reddish gray with pale spots above the eyes, brown bands and spots on the body and limbs, and an obscurely ringed tail. Both species prey upon small mammals, birds, and reptiles, and are not averse to fruits. Several other species are described.

**GENEVA**, a S. E. county of Alabama, bordering on Florida and intersected by the Choctawhatchee and Pea rivers; area, about 550 sq. m.; pop. in 1870, 2,957, of whom 227 were colored. Pine forests abound; the soil is sandy and poor. The chief productions in 1870 were 53,642 bushels of Indian corn, 4,900 of oats, 22,039 of sweet potatoes, 4,749 of peas and beans, 420 bales of cotton, and 40,657 lbs. of rice. There were 2,148 milch cows, 5,125 other cattle, 4,222 sheep, 8,874 swine, and 408 horses. Capital, Geneva.

**GENEVA**, a village of Ontario co., New York, beautifully situated at the N. W. extremity of Geneva lake, on the New York Central and the Geneva and Ithaca railroads, 100 m. E. of Buffalo; pop. in 1870, 5,521. The principal street runs parallel with the bank of the lake, at an elevation of 100 ft., and from many of the residences terraced gardens extend to the shore. It commands a fine view of the lake and of the surrounding country. Geneva is handsomely built, and contains many large

stores. One of the Episcopal churches is a fine stone structure in Gothic style, and was built at an expense of \$40,000. Steamers ply daily on the lake, which is open throughout the year, between Geneva and Watkins, at the opposite extremity, touching at intermediate places. There are six hotels, two national banks, gas works, marble works, two iron works, bending works, a flour mill, a malt house, &c. The nursery business is the chief branch of industry, employing 13 firms and many individuals. The nurseries cover over 3,000 acres, and furnish occupation to from 600 to 700 men and boys. The value of the stock is about \$1,800,000, and the annual shipments of trees, &c., amount to over \$300,000. Hobart Free college (called Geneva college till 1853) was established here in 1824, under the direction of Episcopalians, and in 1872 had 9 professors, 44 students, a library of 12,000 volumes, and a well appointed observatory. The union public school, a fine brick building costing \$30,000, and its four branches, have about 1,200 pupils. A Roman Catholic school is in process of erection. There are two private schools for girls and one for boys, two weekly newspapers, and eight cl

**GENEVA** (Fr. *Genève*; Ger. *Geny*; Eng. *Geneva*). 1. A canton of Switzerland, bounded by Vand and the lake of Geneva, other sides by France; area, 108 sq. m.; pop. in 1870, 93,289, of whom 47,000 were Protestants, 771 Catholics, and 981 Christians; 30,209 German, 121 Italian, and the rest French. The canton speaks a patois, which is what that spoken in the mountains, and its highest point is 500 ft. above the lake. The soil is stony, and therefore not very fertile. The climate is the consequence of the excellent position, which resembles a garden. The canton is situated southwesterly from the lake, and receives the Arve, Nante de Saône, Rhodan, and Laire. The canton is divided into three districts and contains 81 of them the Catholics are 17 the Protestants. The canton has 15 or secondary schools, and 15 schools with 5,600 pupils. The expenditures are about 1,000,000 francs, and the public debt about 1,000,000 francs. The legislature, called the *grand conseil*, consists of one representative for every 100 inhabitants. Geneva was the first Swiss city to introduce trial by jury (1844). The liberal influence upon the Swiss government, the promulgation of the federal constitution in 1848. The canton has a lower house of the *grand conseil*, contingent to the army, and the Protestant churches are 15, and the consistory, which is the executive of the canton.

composed of 25 lay members and 6 clergymen. The *compagnie des pasteurs*, which comprises all clergymen and professors of theology, presides over the religious instruction of the Protestant population, and controls ecclesiastical appointments. The Catholics of the canton, who are divided into 28 parishes, formerly belonged to the diocese of Lausanne. In 1872 the pope erected it into a diocese, a measure which the government of the canton denounced as contrary to the law, insisting that a new diocese could be erected only with the consent of the government. The free "Evangelical Church," which is unconnected with the state, has a theological school in the city of Geneva, and had in 1872 eight clergymen. The administration of education is in the hands of the government, but the parishes are called upon to contribute toward its support. II. A city,

capital of the canton, at the W. extremity of the lake of Geneva, where the Rhône issues from it, and 3 m. above the confluence of the Arve; pop. in 1870, 46,774, of whom 25,897 were Protestants, 20,284 Catholics, 519 members of other Christian denominations, and 574 Jews and other non-Christians. Including the suburbs, the population in 1870 was 57,697. The old city, on the left bank of the Rhône, is hilly and narrow. It was enlarged in 1850 by the conversion of the fortifications into promenades and quays. On the right bank is the more modern part, where the streets are mostly straight and wide. The two parts are connected by six bridges. The Mont Blanc bridge, near the lake, is magnificent. The cathedral, dedicated to St. Peter, erected in the beginning of the 12th century, in the Byzantine style, is believed to occupy the site of an ancient tem-

Geneva.

ple of Apollo. The hôtel de ville formerly had a number of inclined planes without steps, enabling the aged senators to ride up to the highest story in their litters or even on horseback. The public library contains about 60,000 volumes and 600 MSS. The Musée Rath is named after its founder and devoted to the fine arts. On a small island of the Rhône, below the Mont Blanc bridge, stands a monument to Rousseau, who was born in Geneva in 1712. Of the churches in Geneva, the Reformed have seven, the Catholics three; there are also one English and one Greek church, and a synagogue. In 1873 all the Catholic churches passed into the hands of the Old Catholics, as they alone took part in the election of pastors ordered by the new church law of the canton. Geneva has celebrated private schools, which

attract many pupils from abroad, and commercial, industrial, artistic, and musical schools. The university of Geneva was founded in 1568, and was reorganized by Calvin and Beza. The college attached to it resembles the English Eton and Westminster schools, and is conducted by masters (*regentes*), under the direction of a rector, a principal, and the professors of the university. The studies at the university embrace belles-lettres, philosophy and science, divinity, and law. The environs of Geneva are dotted with villas. The suburb Plainpalais is regularly built, and has about 8,000 inhabitants. Les Eaux Vives, a suburb on the road to Chamouni, has a population of about 6,000. In the vicinity is a celebrated lunatic asylum in a magnificent edifice.—Geneva has long been celebrated for its manufacture of

watches, jewelry, and musical boxes, employing about 3,000 persons, who make more than 100,000 watches a year, and work up annually about 75,000 ounces of gold, 5,000 marks of silver, and \$200,000 worth of precious stones. There are also manufactories of velvet, silk goods, India stuffs, hats, leather, cutlery, firearms, chronometers, and mathematical, musical, and surgical instruments. Geneva became a free port in 1854. The transit trade is considerable, and the neighborhood of France and Italy gives rise to active smuggling. The forwarding, commission, and banking business, especially the latter, are of great magnitude. Geneva is also the principal telegraph station and the focus of the railways of Switzerland, and the central point of the federal postal and customs union.—Calvin lived in Geneva, and Servetus was burned at the stake in the *champ du bourreau*, the ancient place of execution, outside the walls. John Knox was made a citizen of Geneva in 1558. Among the distinguished persons born in the city are Jean Jacques Rousseau, Necker, the naturalists De Saussure, Deluc, Bonnet, Huber, and De Candolle; Dumont, the friend of Mirabeau and of Jeremy Bentham; Sismondi the historian; and Albert Gallatin, the American statesman. Sir Humphry Davy died and was buried in Geneva. Guizot the French statesman, whose mother found an asylum in Geneva, received his early education there.—Geneva is supposed to have formed part of the territory of the Allobroges. It was subjected to the Romans about 122 B. C. The city was burned during the reign of Heliogabalus, and rebuilt by Aurelian, who gave it many privileges and called it Aurelianum Allobrogum. In the 5th century it was annexed to the possessions of the Burgundians, and in the 6th to the Frankish kingdom. The republic of Geneva originated in the municipal institutions of the town, to which Charlemagne granted certain privileges, subordinate to the bishop, who was called prince of Geneva, and was an immediate feudatory of the German empire. Dissensions occurred on many occasions between the citizens and the bishops on one side, and the counts of Genevois, who ruled the adjoining province of Savoy and claimed jurisdiction over Geneva, on the other. After the extinction of the line of the counts of Genevois, the dukes of Savoy were appointed their successors by the German emperor Sigismund (1422). Hence the claim of Savoy upon Geneva, from which the Genevans could only free themselves after several centuries by alliances with other Swiss states, and by the aid of the reformation. The bishop of Geneva was expelled in 1534. Through the zeal of William Farel, the new service of the reformed religion was established in August, 1535. But the old parties, the partisans of Savoy and the national party, reappeared under new forms and fomented discord. Farel prevailed upon Calvin, who came to Geneva in August, 1536, to remain there, and eventu-

ally made himself the temporal as well as spiritual ruler of the town. Geneva became the leader of religion and the model of morals in Europe, the home of literature and learning, and the metropolis of Calvinism. An attack of Charles Emanuel of Savoy upon Geneva (December, 1602) was gallantly repelled, and the victory then achieved is still commemorated. The independence of Geneva was solemnly recognized by the house of Savoy in 1734. The government of the city fell into the hands of patrician families, as everywhere else in Switzerland, and the history of this century becomes a list of fierce and often bloody struggles to regain the old rights and privileges belonging to the people. In 1782 the administration party obtained the interference of France, Sardinia, and Bern, who sent troops into Geneva and oppressed the democrats. In consequence, about 1,000 Genevese applied for permission to settle in Ireland, and the Irish parliament voted £50,000 to defray the expense of their journey, and gave them lands near Waterford; but they soon abandoned the settlement. Other fugitives stirred up the French republicans to invite Geneva to France, and in 1798 the town was occupied by French troops and incorporated with France as a part of the department of Léman. After the overthrow of Napoleon's joined the renewed Swiss confederacy (March 20, 1815), and several places which had formerly belonged to France and Savoy were added to its territory. A new and liberal constitution was adopted.

The Geneva convention of 1864, an agreement among the 100,000, consider the edifices and the judicial departments strictly new. In 1868 naval wars were ended by this treaty. The United States, however, not join in it. In December, 1871, of arbitration on the basis of a committee consisting of five members of the United States, Italy, Switzerland, and the deposed duke of Brunswick. On Aug. 19, 1873, and left to the city fortune, about 100,000,000.

**GENEVA**, Lake of, or *Léman*), the largest lake in Europe, extending in the form of a crescent, with horns toward the north and the south, and the east toward the Alps and Valais. Its N. end is 53 m. long, exclusive of the lake of its S. shore it measures 46 m. It varies from 8 or 10 m. near the E. and 1 m. near the W. area, about 240 sq. m. The lake is on a line bearing N. 30° E. is about 1,000 ft.; at the N. end it is 1,500 ft. Its elevation above sea level is 1,950 ft., but in summer, when the snow melts, it sometimes rises to 2,000 ft. In other periods it presents a level of the lake, most common

curious phenomenon of a rise and fall of from 2 to 5 ft. in the course of 25 minutes. These changes of level, called *seiches*, have never been fully accounted for, but are supposed to be owing to the unequal pressure of the atmosphere upon different parts of the surface. They are independent of the wind, and most frequent when the clouds are low and heavy. The lake is never frozen over, though ice forms in winter near its lower extremity. Its waters are pure and bright blue, like those of the Mediterranean. The Rhône enters it at the E. end a dark muddy stream, and leaves it near Geneva perfectly pellucid and of the finest azure hue. The débris brought down by this stream are deposited around the upper end, and have made considerable encroachments upon its basin. Port Valais, 1½ m. inland, was formerly situated on the shore, and the waters are said to have extended as far as Bex, 12 m. up the Rhône. About 40 small streams discharge themselves into this lake. It has fewer fish than other Swiss lakes, but contains excellent trout, pike, carp, and perch, and a kind of salmon. Steamers ply daily between Geneva at the W. and Villeneuve at the E. end. The scenery is an unfailing theme of admiration to travellers. On the north are beautiful vine-covered hills dotted with villages; opposite, the abrupt cliffs of the Chablais rise 5,000 ft. above the lake. The majestic Alps are seen beyond them through the openings. On the east, between the lofty summits of the Dent de Moreles and the Dent du Midi, about 9,000 ft. high, a narrow pass opens into Valais, while at the W. end the lake narrows almost to a point, and terminates among the pleasant slopes on which stand the city and suburbs of Geneva. The lake is famous in literary history as the scene of the *Nouvelle Héloïse*, and for the abode in its vicinity of many celebrated authors.

**GENEVIÈVE. I.** The patron saint of Paris, born in Nanterre about 422, died in Paris in 512. According to the most common tradition, her parents, Severus and Gerontia, were very poor, and Geneviève's early occupation was tending flocks. On the summit of Mont Valérien is a field which still bears her name, as well as a spring and grotto at its foot. In her 15th year she was dedicated to the divine service by St. Germanns of Auxerre. She predicted in 449 the invasion of the Huns under Attila, and when in 451 he threatened to attack Paris, her prayers were believed to have saved that city. Again, during the protracted siege of Paris by the Franks under Clovis, she animated the courage of the citizens, and contrived to introduce into the city a supply of provisions. When Paris fell, Geneviève's intercession saved the vanquished from harsh measures. She was revered by Clovis, and was buried near him in the church of Sts. Peter and Paul, which he had built, and which together with the adjoining abbey bore her name. Her shrine, said to be the work of St. Éloi, was replaced in the 13th century by one much larger and richer,

which was long considered the palladium of Paris. It was sent to the mint in 1791, and the relics it contained were burned. A monumental church, begun by the architect Soufflot in 1757, was named the Pantheon in 1791, and restored to public worship in 1852, under the title of St. Geneviève. The stone sarcophagus which formerly contained her remains has been transferred to the church St. Étienne-du-Mont. The life of St. Geneviève, written by her contemporary Genesius, was restored to its original simplicity by the Bollandists, and republished in 1648 in the *Acta Sanctorum*. Her feast is celebrated on Jan. 3. **II.** A daughter of the duke of Brabant, born about 680. Hagiographers and historians have spoken of Geneviève de Brabant sometimes as a canonized saint, sometimes as only beatified; the Bollandists say her feast was kept in April; but she was never acknowledged as a saint by Rome. Her history, the subject of so much romance and poetry, may thus be condensed from the best sources. She was married about 700 to Sigfrid, count palatine of Ostendick in the territory of Treves. He was summoned to attend Charles Martel on his expedition against the Saracens, leaving his wife and estates to the guardianship of one of his knights named Golo. The lady, whose pregnancy was not known to her husband, had now to resist the criminal solicitations of Golo, who after the birth of her boy accused her of adultery, and obtained from Sigfrid an order to put mother and child to death. Instead of executing this order, Golo abandoned them in a forest, where they subsisted for several years, until they were discovered by Sigfrid during a hunt, and carried back in triumph to his castle of Hohen-Simmern. Geneviève, in thanksgiving for her preservation, had a chapel built on the spot which had sheltered her babe and herself. The ruins of this chapel, called Frauenkirchen, are still visible, and contain, together with the despoiled tombs of Geneviève and Sigfrid, an altar on which are rudely sculptured the main facts of their history.

**GENGHIS (or Zingis) KHAN**, an Asiatic conqueror, born about 1160, died in August, 1227. His father was the chief of a horde, consisting of numerous families or clans, and tributary to the khan of eastern Tartary. When born, the child had his hand full of blood; and, pleased by the interpretation of this sign as a prediction of conquest and glory, the father procured for Genghis, or, as he was then called, Temudjin, an able teacher, who soon developed in him a talent for government and war. Temudjin was only in his 14th year when he succeeded his father, and after some reverses he made himself master of the neighboring tribes, 70 of whose chiefs are said to have been thrown into kettles of boiling water at his command. Against a league of more numerous tribes he was also victorious, but was unable to subdue them, and compelled to invoke the protection of Vang or Ung, the great khan of

the Keraite Tartars. Temudjin supported him in his turn in different wars, and received the daughter of the khan in marriage. But his bravery, liberality, and success soon made him an object of envy and fear; a war ensued, in which the khan lost his army on the battle field, and his life while in flight. Another enemy of Temudjin, Tayan, khan of the Naiman Tartars, met with a similar fate in and after the battle of Altai, which gave Temudjin a great part of Mongolia and the capital Karakorum. In the next spring he held a great assembly of his nation at Blun-Yulad, his capital, where the representatives of all the hordes appeared and proclaimed him their great khan. Then, obeying the words of a *shaman* (inspired man), who promised him the conquest of the earth, he adopted the title of Genghis (greatest), and gave to his people that of Mongols (the bold). He organized their civil and military system, and laid down a code of laws which is still known in Asia under his name, and is based upon the belief in one God and the monarchy of one great khan, to be elected from the reigning family by the *kuraltai*, or assembly of the nation. It grants great privileges to the nobles, allows polygamy, forbids to conclude peace except with the vanquished, and commands the delivery of arms into the hands of the government in times of peace, and when no national hunts are held. He granted equal rights to every religion, and admitted men of talents or merit to his court, whatever their creed. Appreciating the wisdom of other nations, he caused many celebrated books to be translated from foreign languages. Ambition soon prompted him to new expeditions. The annexation of the Ugrian or central Tartars served to complete the conquest of Tartary; he now commenced that of China, passed the great wall, vanquished the opposing armies, plundered and destroyed 96 cities, reduced to ashes smaller towns and villages, and carried away multitudes of children, who were destroyed in the homeward march, besides a vast spoil of cattle, gold, silver, and silk. In a second expedition he was equally successful. He devastated the country, and in 1215 took Yehking (now Peking) by assault. This great city was pillaged and burned. Giving the command in the east to his son Tutshee, Genghis now turned his sword to the west, crushed some revolted tribes and their allies, and took a bloody revenge for the murder of his ambassadors on Mohammed, sultan of Kharesmia. A vast army, and the cities of Bokhara, Samarcand, and others, opposed him in vain. The Mongols conquered and devastated the whole country; the cities were destroyed, and with them immense treasures of eastern science and art; and numberless inhabitants were slaughtered or carried away as slaves. Another Mongol army marched against Kaptehak, and took Derbend on the shore of the Caspian sea; another reduced Iran and Astrakhan, and, after a bloody battle on the Kalka, south-

ern Russia; another continued the conquest of China and subdued Corea. The countries N. W. of India were also conquered, and an expedition against that country was begun. In this he is said to have shared the fate of Alexander the Great in a similar undertaking: after some victories, the army refused to advance further, and he was compelled to return amid terrible difficulties. He then turned his arms against the kingdom of Tangut, passed the desert of Gobi in winter, and defeated 300,000 men on a frozen lake; the Tangut dynasty was extirpated. He was meditating new conquests when death ended his career. He was buried in his native home, and his funeral was celebrated with songs, and some historians say with a hecatomb of beautiful young girls. His empire was divided among his four sons, Oglutai, chosen great khan, Jaggatai, Tului, and Tutshee, whose armies soon completed the conquest of China, overthrew the caliph of Bagdad, made the sultan of Ikenium tributary, and penetrated as far as the Oder and the Danube.

**GENIL.** See MYTHOLOGY.

**GENLIS, Félicité Stéphanie Dacrest de** countess de, a French authoress. Born Autun, Jan. 25, 1746, died in Paris, 1830. She had a taste for music, and great proficiency on the harp, and on other instruments; but her education was almost entirely neglected. When years of age she was married to Count de Genlis, a friend of her father, who had fallen in love with her on seeing her. Full of ambition, she then devoted herself with great zeal to study. By the influence of her aunt, Mme. de Montesson, who was secretly married to the duke of Orleans, she was in 1770 appointed a lady-in-waiting in the household of his daughter, the duchess de Chartres, became governess of the daughter of the duke of Orleans, and was formally nominated in 1782 by Louis de Chartres (afterward duke of Orleans) "governess" of his three sons, the elder of whom was afterward King Louis Philippe. The title given to a woman gave rise to much scandal, and the influence she subsequently exercised upon the political career of the emperor, the notorious Philippe, and to warrant the most injurious statements concerning her governorship she published works devoted to the moral education of pupils—the *Théâtre d'éducation*, *Antigone*, *Adèle et Théodore*, *Les veilles de la nuit*—which were popular with the public, and were translated into English, La Harpe, and others. During the first years of the revolution she proclaimed her liberal opinions, and have been the principal authors of the *Égalité*. She published *Considérations sur l'éducation du dauphin*, and *Leçons d'éducation* written in the spirit of the revolution. She was, however, obliged to

1793 retired for a while to Switzerland, and then to Altona. Amid all her troubles she neglected no opportunity of mingling in worldly pleasures. During this period she published several works, among which were her *Mémoires*, *Les petits émigrés*, and *Le petit La Bruyère*. In 1800 she returned to France, and was well received by the first consul; she was allowed handsome apartments at the arsenal and a pension of 6,000 francs, to which the wife of Joseph on his accession to the throne of Naples added an annuity of 3,000. In return for this she had to write twice a month to Napoleon, and communicate to him her opinions and observations on politics and current events. It is not known what service she rendered to Joseph Bonaparte. This period of comparative repose and prosperity was also one of literary activity; she gave to the public, among other works, *Mlle. de Clermont*, the best of her performances, which ranks among standard novels in the French language, *La duchesse de La Vallière*, *Mme. de Maintenon*, and *Le siège de La Rochelle*. Her *Histoire de Henri le Grand* displeased Napoleon, and she lost her pension and residence. At the return of the Bourbons the Orleans family contented themselves with paying a small pension to their old "governor." Her temper meanwhile, which never had been very gentle, became sullen and unmanageable; her misanthropy increased with years. Her wrath was especially directed against the philosophers of the last century; she published amended editions, with critical notes, of several works of Rousseau and Voltaire, and even contemplated a similar "emendation" of the *Encyclopédie*, but, appalled at the magnitude of the undertaking, gave it up, and turned her pen against the most popular contemporary authors. Mme. de Staël, Byron, Sir Walter Scott, and Lamartine were among the objects of her attacks. She was 60 years old when she published her historical novel *Jeune de France*, and over 80 when she completed her personal *Mémoires*, in 10 large 8vo vols.

**GENNESARET**, or *Genesareth*, Lake of, called also the sea of Chinnereth (Heb. *Yam Kinnereth*), the sea of Galilee, the sea of Tiberias, and by the Arabs *Bahr Tubariyeh*, situated in Palestine, 6½ m. N. of the Dead sea. The lake is pear-shaped, the greatest width is 6½ m. from Mejdal (Magdala) to Kheraa (Gergesa); the extreme length is 15 m. The Jordan enters it

muddy at the north, and passes out pure and bright at the south. The water of the lake is clear and sweet, except near the salt springs and where it is defiled by the drainage of Tiberias. In the basin of the lake are a number of warm springs, which are said to have in-

Lake of Gennesaret.

creased in volume and temperature after the earthquake of 1837, which laid Tiberias in ruins. The lake does not appear to be of volcanic origin, but simply part of the great Jordan depression. The surrounding hills are of a uniform brown color, and are limestone, capped in places with basalt; they are recessed from the shore, or rise very gradually from it, and not very high. Its level, which varies at different times of the year, is between 600 and 700 ft. below that of the Mediterranean. There is little variety or beauty in its natural features, and the interest connected with it springs from its associations, especially from the fact that much of the public life of Christ was spent on its shores. The lake abounded with the choicest kinds of fish, as it does now, and the southern portion especially was a noted fishing ground. Populous cities and villages then flourished around it, as Tiberias, Magdala, Capernaum, Chorazin, the two Bethsaidas, Gama-la, and Hippos, almost all of which are now uninhabited ruins.

**GENOA** (Ital. *Genova*; Fr. *Gènes*; anc. *Genua*). L. A N. W. province of the kingdom of Italy, bordering on the provinces of Porto Maurizio, Coni, Alessandria, Pavia, Piacenza, Parma, and Massa Carrara, and the gulf of Genoa; area, 1,588 sq. m.; pop. in 1872, 716,284. The province is divided into the districts of Albenga, Chiavari, Genoa, Levante, and Savona. It forms a narrow coast land, called Riviera di Levante and Riviera di Ponente, around the gulf of Genoa, and embraces the former duchy of Genoa. The rivers, mostly springing from the Apennines, have but a short

course through this province, either emptying into the gulf or passing over to the adjacent provinces. Agriculture is unimportant, for want of level land, but the hills are covered with vines and olives, and furnish delicate fruits which are largely exported; bee-keeping is a lucrative industry of the mountaineers. There are silver, copper, lead, manganese, and coal mines; and the slate quarried near Lavagna is celebrated for its deep, lustrous black color. The Ligurian Apennines touch the Ligurian Alps near the sources of the Bormida, where the road from Millesimo to Savona climbs three mountain ridges from 1,500 to 2,300 ft. high. From here the Ligurian Apennines extend along the coast of the gulf in three distinct chains, separated by deep depressions: the Monte S. Giorgio, N. W. of Savona; Ermetta and Reisa, N. W. of Voltri; Penello, Orditano, and Secco, N. W. of Genoa.

North of this city are the Monte della Bochetta, 2,432 ft. high, and the Colli dei Giovi 1,447 ft., with a double pass that permitted the construction of a turnpike and a railway to Alessandria. East of these the Apennines rise much higher. N. E. of Genoa is Monte Antola, 4,151 ft. high. N. E. of Chiavari, near the boundary, is Monte Penna, 5,360 ft. high. From Genoa to Antivari, and from Lavagna to Spezia and Porto Venere, close to the coast are mountain chains 2,000 to 3,000 ft. high. The mountainous peninsulas, Portofino and Castellana, form S. E. of Genoa the gulfs of Rapallo and Spezia, of which the latter is important as a safe and commodious port for the Italian fleet. A railway skirts the entire coast of both Rivieras, and runs parallel with the magnificent highway called the Cornice road. The line penetrates numerous promontories by more than 30 cuttings and tunnels, many of

Palazzo Doria.

them of considerable length, in a distance of 24 m., between Genoa and Chiavari. Another railway through the province, connecting Genoa with Alessandria, has nine tunnels between Arquata and the capital. The last tunnel before reaching Genoa, called the Galleria dei Giovi, is more than 2 m. long. II. A city, the capital of the province, on the N. extremity of the gulf of the same name; lat. 44° 24' N., lon. 8° 54' E.; pop. in 1872, 130,269. It is surrounded by a double wall, the smaller encircling the inner city, by ramparts and extensive outworks, detached forts, and redoubts, which make it one of the best fortified cities of Europe. Its large semicircular harbor is defended by two converging moles, the eastern or old, and the western or new. In the height of her power the city was called Genova la Superba (the proud); and the designation has also been used in the sense of "mag-

nificent," on account of her beautiful and numerous marble palaces. On the N. side is the royal war harbor (arsenale) with the marine arsenal. (C. 1872) the free harbor (porto franco). The walled town of Genoa contains 300 large storehouses. No man or woman is allowed to enter without special permission. A bridge separates the harbor from the city, and the piazza di S. Marco is connected by rail with the harbor. Viewed from the harbor, the city is an amphitheatre, with its streets, promenades, and gardens, and fortifications, and with the Ligurian Apennines and the ice-covered Alps behind, offers one of the most picturesque sights in

streets are mostly narrow, irregular, and steep, paved with smooth slabs of lava, with a pathway of bricks in the centre for mules; but the *vie Balbi*, *Nuova*, and *Nuovissima* are broad and straight; and the more modern *vie Carlo Felice*, *Carlo Alberto*, *Carretierra*, and *Giulia* compare favorably with the chief thoroughfares of other commercial cities. The splendid architecture of the palaces, the external frescoes of the houses, the imposing religious processions, and the varied attire of the passengers, the ancient attractions of the city, are all gradually disappearing. The *mezzaro*, the long white veil with which the women formerly covered head and shoulders, is now rarely seen except on Sunday when they go to mass. The palaces were once renowned for their artistic riches, but the collections are constantly diminishing, and have become very small. The most striking of the palaces is the palazzo Doria, in a conspicuous position overlooking the sea. It was constructed in 1529 by the renowned Doria, prince of Melfi; it is now almost abandoned, and retains but few traces of its former beauty. The ducal palace, restored in 1778 after designs by Simone Carlone, was formerly full of objects of art, which have been removed, some of them to the municipal palace, formerly the palazzo Doria Tursi. In the anteroom of the hall of the town council are a bust and autograph letters of Columbus. The Carlo Felice is one of the largest and finest theatres in the kingdom. That of Sant' Agostino is built entirely of wood, and can accommodate 2,000 spectators. A new café, with a garden and fountains, is one of the most splendid establishments of the kind in Europe. The *dogana*, or custom house, is the ancient edifice of the bank of St. George, and has in the hall two ranges of statues, larger than life, of the Dorias, Fieschi, Grimaldis, and other renowned personages of the old republic. Among the numerous churches, that of Santa Maria di Carignano is prominent for architectural beauty. The cathedral, dedicated to San Lorenzo, presents a strange mixture of styles. It was built in the 11th century, and has been restored many times. The richest part is the chapel of St. John the Baptist, into which no woman can enter except on one day in the year, in recollection of the daughter of Herodias. In it is preserved the *sacro catino*, affirmed to be one of the gifts of the queen of Sheba to Solomon, and the vessel from which Christ ate the paschal lamb. It was a part of the spoil taken at Cæsarea in 1101. It was long supposed to be cut from a single emerald, but is now known to be glass. In the piazza di Acqua, a public promenade, stands a statue of Columbus on a circular pedestal with protruding prows of galleys; at the feet of the statue kneels the figure of America. Genoa has a university with an observatory and a library of 50,000 volumes, a naval school, a lyceum, technical schools, seminaries, normal schools, and many societies for the promotion of arts and sciences.

The foundling hospitals, orphan asylums, hospitals for the sick, crippled, insane, and deaf, and poorhouses, are in a praiseworthy condition. About two miles from the city is the *campo santo* (cemetery), with a magnificent circular chapel and many artistic monuments and vaults. The most delightful excursion in the environs is to the villa Pallavicini at Pegli, where the park extends to a considerable height on the slopes of the coast, affording charming views of Genoa, the sea, and the mountains. Luxuriant vegetation, kiosks in Pompeian, Turkish, and Chinese styles, a mausoleum, the remains of an ancient Roman burial place, and a stalactite grotto heighten the interest of the place.—The railway to Alessandria brings to Genoa a large trade with the provinces of northern Italy, Austria, Germany, and Switzerland. Cotton industry employs about 3,000 workmen, and about 9,000 are employed in the manufacture of silk goods. There are large establishments producing lace, embroideries, and filigree work. The hat factories export yearly about 100,000 hats to South America. Other considerable industries are the extraction of oil, the fabrication of soap, the preparation of chemicals, the making of artificial flowers, and the packing of candied fruit. The furniture factories employ several thousand workmen, and the construction of boats and ships is steadily increasing. In 1871 vessels of the aggregate tonnage of 50,000 were launched. Among them were two iron steamers, the first iron vessels built in Italy. Genoa is a free port. About 7,000 sailing vessels of 700,000 tons, and 3,000 steamers of 600,000 tons, enter every year. In 1871 the entries of vessels engaged in foreign trade were 3,009, with an aggregate tonnage of 934,263; the tonnage of coasting vessels entering in the same year was 406,265. The total imports amounted to \$51,500,000; exports, \$22,250,000. Numerous lines of steamers ply between Genoa and Leghorn, Civitavecchia, Spezia, Naples, Messina, Nice, Tunis, and other ports on the Mediterranean. The population of Genoa has increased but little during the past ten years, on account of the excessive octroi duties levied on almost everything that passes the gates. To escape these, many people have settled in the neighboring communes, and Sampierdarena and other villages have grown largely in consequence.—The history of Genoa may be traced in legendary traditions to a time preceding the foundation of Rome. Livy mentions it first, at the beginning of the second Punic war, as a town in friendly relations with the Romans. It was subdued and partly destroyed during that war by a Carthaginian fleet, which sailed from the Balearic isles under the command of Mago; the Romans rebuilt it, and it afterward became a Roman *municipium*. In the time of Strabo it was an emporium for the produce of the interior, exchanged by the Ligurians for the wine and oil of other parts of Italy. After the fall of the western empire it suffered greatly from the in-

vading Goths, was taken by the Lombards in the 7th century, and conquered from them in the 8th by Charlemagne, who appointed a count for the government of the coast of Liguria. After the dismemberment of the Frankish empire, it became independent, and shared the fate of the Lombard cities, participating in their bloody struggles during the long contest for the iron crown of Lombardy between the emperors of Germany, the Berengarii, and others. After having been pillaged in 936 by the Saracens, Genoa strengthened its navy, entered into an alliance with Pisa, and expelled the Mohammedans from the islands of Corsica, Capraja, and Sardinia (1016-'21), of the two former of which it kept possession. But the increasing maritime importance of the Genoese aroused the jealousy of their commercial neighbors, and they had to struggle for the maintenance of their power in the western part of the Mediterranean against the rival republic of Pisa, and in its eastern part against Venice. The hostilities with the former commenced in the year 1070. The services of the Genoese in the first crusade were rewarded with a strip of the coast of Palestine. After the second war with Pisa (1118-'32) they undertook an expedition against the Moors of Spain, with a large fleet carrying a land force of 12,000 men, conquered the island of Minorca (1146), Almeria (1147), where they found immense booty, and, in concert with the Catalonians, Tortosa (1148). Their power was also rapidly extended over the coast of the Mediterranean; before the close of the 12th century they were masters of Monaco, Nice, Montferat, Marseilles, and nearly the whole coast of Provence. The third struggle with Pisa commenced in 1162, and lasted for nearly a century. The early part of the fourth was marked by a great naval victory near Meloria (1284) of the Genoese over the Pisans, who lost 3,000 killed and 13,000 prisoners, most of whom were doomed by the cruelty of the victors to perish in chains; it was virtually ended by the conquest of Elba, and the destruction of the harbor of Pisa, under Corrado Doria (1290). Thus peace was conquered, and the power of the rival republic destroyed. No less severe had been the struggle with Venice since the conquest of Constantinople by the Franks (1204). Having assisted Michael Palæologus to reconquer the capital of the Byzantine empire (1261), the Genoese were rewarded with the suburbs of Pera and Galata, and the port of Smyrna, which made them masters of the Black sea. This brought them into collision with the Venetians, who disputed their supremacy in those seas; but after several naval battles a truce was concluded in 1271. On the termination of the wars with Pisa a powerful Genoese fleet crossed the Adriatic, and won a great victory near Curzola, where 84 Venetian galleys were taken or burned, and 7,000 captives made, among them the admiral Dandolo. This was followed by a treaty of peace (1299),

which surrendered the commerce of the Black sea to the exclusive dominion of the Genoese, whose flourishing colonies and factories defended by forts soon lined all its coasts. Caffa, or Feodosia, in the Crimea, became one of the finest commercial cities of Europe. Favored by the friendship and indolence of the Byzantines, they carried on the commerce of the East including India, through the Black and Caspian seas. A new war with Venice broke out in 1346, in which the Genoese were victorious in a sea fight in sight of Constantinople, but were beaten in another near the coast of Sardinia. To escape the consequence of this defeat and the perils of intestine commotions, they subjected themselves to the duke of Milan, Giovanni Visconti, whose yoke, however, they soon shook off. Having recommenced the war (1377), they took Chioggia, besieged Venice, and nearly reduced it, when two of its citizens, Vettor Pisani and Carlo Zeno, revived the spirit of the besieged, created a new fleet, blockaded Chioggia, and compelled the Genoese to surrender. The peace of Turin (1381) terminated the wars of the two greatest maritime republics of the middle ages; it was served with slight interruptions during the decline of both, caused particularly by quests of the Turks in the East and the time discoveries in the West. Giustiniani and his companions strove heroically, but to save the great bulwark of Constantinople, and the interests of the empire (1453); and Mohammed II. revived the power of the republic by stripping the republic of all its power in the East; even the commercial supremacy of the Euxine was soon closed by the Turks. All this growth and decline of the republic, its internal commotions, caused by the divisions of the plebeians and patricians, and the divisions of the latter, had been attended by continual perils and distractions. The republic governed by consuls till 1118, then by annual magistrates, who were chosen from foreign cities) till 1270, it fell into the hands of Oberto Spinola, one of the "captains of liberty," who gave power to the lower classes and maintained the republic till 1291. A new change was made by a council consisting of 12 patricians and 12 plebeians, and even fights of the democratic parties, the Guelphs and Ghibellines, were meanwhile continuing, whose chiefs were the Doria and Spinola families, was at last overthrown by its opponents, headed by the Doria family, but afterward revived. These party struggles continued till the first half of the 14th century, when by these evils the republic was brought to its end (1389), with the extinction of the Doria family. But neither the peace of Turin nor the peace of the councils was sufficient to give peace to the distracted state; new conflicts arose between the families; there were

some were exiled, others forced upon the people. The Viscontis of Milan, and at a later period the kings of France, availed themselves of these dissensions to take possession of the republic. Francis I. held it during the first part of his wars with Charles V., but in 1528 the celebrated admiral Andrea Doria delivered the state from the French, and established a new constitution, which lasted to the end of the republic. The new form of government was strictly aristocratic; a roll of families, both plebeian and patrician, was formed, the nobility divided into the old and new; the former comprised the Grimaldis, Fieschi, Dorias, Spinolas, and 24 others distinguished by age, honors, or riches, and the latter 437 houses, to which new families could be added; the doge was elected for two years, and both branches of the nobility could aspire to this dignity. But the power of the state had long since departed; its conquests, colonies, and maritime stations were lost one after another; the last of them, Corsica, revolted in 1730, and was ceded to France in 1768; the commerce of the seas and of the East passed successively through the hands of the Portuguese, Spaniards, Dutch, and English; the flag of Genoa was insulted with impunity by the Mohammedan pirates of northern Africa, and its naval force was a mere shadow of the ancient fleets which awed all the shores of the Mediterranean and Black seas. The single bank of St. George (*compera di San Giorgio*), which had been founded in 1407, still maintained its importance as an institution for loans and deposits, to which even foreign states, and particularly Spain, were greatly indebted. When in 1796 the French had conquered the neighboring territories, Genoa strove in vain to sustain itself by neutrality. A rising of the democratic party was suppressed, after several days of bloodshed, by the nobles, who were assisted by the poorest of the population; but the French directory took the part of the democracy, and demanded a change in the constitution. This demand was supported by an army, and finally agreed to. The French garrison was taken into the city, and the state changed into the republic of Liguria, with a constitution like that of France, and some additional territory. In 1800 Genoa, under Masséna, sustained a siege by the Austrians and English, and was compelled to capitulate to the former, who were obliged, however, to give it up after the battle of Marengo. Bonaparte, as first consul, gave it a new and less democratic constitution, which was soon abolished on the establishment of the French empire. After the coronation of Napoleon at Milan, the last of the doges, Durazzo, repaired to that city, and expressed the desire of the people for the change; and the decree of June 4, 1805, merged the republic in the empire, to form the three new departments of Genoa, Montenotte, and the Apennines. The bank of St. George, whose credit had suffered greatly by repeated loans to the state,

was abolished, and the debts of the latter were transferred to the account of France. In 1814 Genoa was occupied by the English, with whose permission the ancient constitution was reestablished. But the congress of Vienna gave Genoa as a duchy to Sardinia. In 1821 it joined for a moment the revolutionary movements of Italy. At the end of March, 1849, after the defeat of Charles Albert at Novara, and the conclusion of a truce with the Austrians, a revolutionary outbreak took place, the national guards occupied the forts, and the garrison was compelled to withdraw. A provisional government, under Avezzana, Morchio, and Reta, was formed, and the independence of the republic was proclaimed. But a large body of Sardinian troops, under Gen. Lamarmora, soon appeared before Genoa; a bloody struggle ensued, and the forts and principal points of the city were taken by the royal soldiery. In the mean while a deputation was sent to Turin, which returned with the amnesty of the king, excluding, however, the chief leaders of the movement, who had withdrawn on board the United States steamer Princeton. On April 10 Genoa was disarmed, and the monarchical government restored. Garibaldi seized two steamships in the port of Genoa in May, 1860, and thence sailed for the liberation of Sicily. Early in 1861 the territory of Genoa was made a province of the kingdom of Italy.

**GENOA, Tommaso Alberto Vittore**, duke of, an Italian prince, born Feb. 6, 1854. He is the son of Victor Emanuel's late brother Ferdinand, and of a Saxon princess, the duchess of Genoa (privately remarried in 1856 to her former secretary, Marquis Rapallo). He was educated at Dr. Arnold's school in England, and was brought forward in 1870 as a candidate for the throne of Spain, but his name was withdrawn at the request of Victor Emanuel. He is an officer of the Italian navy, and visited China and Japan in 1873, and the United States in 1874.

**GENOUDE** (originally GENOUD), **Antoine Eugène de**, a French journalist and author, born in Montélimart in February, 1792, died in Hyères, April 19, 1849. He was the son of a cabaret keeper. He began his career as a political writer for the royalist journal *Le Conservateur*. In 1820 he founded the journal *Le Défenseur*, and in 1821 he bought the *Étoile*, which has since borne the name of *La Gazette de France*. He abandoned his intention of entering the priesthood when, in 1822, he was ennobled by Louis XVIII.; but in 1835, after the death of his wife, he took orders, and began to preach in Paris. The archbishop of Paris soon ordered him to quit either preaching or journalism, and he quit preaching. In 1846 he was elected by the city of Toulouse to the chamber of deputies, where he acted with the legitimist opposition. He differed, however, in many points from the legitimist party, defending universal suffrage, national representation, and legitimacy allied with popular sovereignty.

In February, 1848, at the outbreak of the revolution, he allied himself with the revolutionary party in order to attempt a restoration of the Bourbons by a general vote of the people. When he saw that his efforts were fruitless he retired from public life. The bold advocacy of his principles in the *Gazette de France* involved him in 63 lawsuits, which cost him more than 100,000 francs. He wrote *Leçons et modèles de littérature sacrée* (1837); *Histoire de France* (16 vols., 1844-'7); a new French translation of the Bible, with the Latin version, a translation of the works of the fathers of the first three centuries, of those of St. Clement of Alexandria, &c.

**GENOVESI, Antonio**, an Italian philosopher and political economist, born at Castiglione, near Salerno, Nov. 1, 1712, died in Naples, Sept. 22, 1769. He received priest's orders in Salerno in 1736, and held in succession the chair of rhetoric in the seminary of Salerno, and that of metaphysics in the university of Naples. He substituted the scientific doubt of Descartes and the Baconian laws of induction for the traditional belief in authority. He was threatened with persecution, but explained his views in a satisfactory manner, and was protected by Benedict XIV. In 1754 a chair of public economy was established in the university for Genovesi, by his friend Interi, a wealthy Florentine, who prescribed as one of the conditions of his endowment that no monk should ever be appointed professor. This chair was the first of the kind in Europe. On the expulsion of the Jesuits from Naples in 1767, he was requested by the government to propose a plan of university education. He advised the establishment of chairs of physical science and history, the substitution of mathematics for scholastic philosophy, and a chair for the interpretation of Cicero's *De Officiis*. His favorite masters in philosophy, after Bacon and Descartes, were Leibnitz, Locke, and Vico. As an economist Genovesi advocated the abolition of the usury laws and of convents and monasteries, inculcated the doctrines of free trade, and proclaimed before Adam Smith the supremacy of labor in the creation of the wealth of nations. As early as 1764 he predicted the emancipation of the American colonies, the foundation of the United States, and the total failure of the colonial system. He died as his friends were reading to him the *Phædo* of Plato. His works include *Elementa Metaphysices*; *Lezioni di commercio o di economia civile*; *Diocæsina*, relating to the rights and duties of man; *Logica dei giovani*; *Istituzioni delle scienze metafisiche*; *Meditazioni filosofiche*; *Elementi di fisica sperimentale*; *Lettere ad un amico provinciale*; and *Lettere accademiche sulla questione se sieno più felici gli ignoranti che gli scienziati*. His life has been written in Latin by Fabroni. G. M. Galanti, one of his best pupils, published in 1771 *Elogio storico dell'abate Genovesi*; and Racciopi's *Genovesi* appeared in 1871.

**GENSERIC** (from *Gaiseric*, prince of the spear), a Vandal conqueror, bastard brother and successor of Gonderic, died in 477. The Vandals had passed the Alps and the Pyrenees and devastated and conquered a large part of Spain. In 429, when the weak and debauched Valentinian III. occupied the throne of the crumbling western empire, they were called to the province of Africa by Boniface, the governor, who had been induced by intrigues and the fear of a rival to betray his master. Eager for conquest, these northern barbarians prepared a fleet, and were ready to embark when the unexpected attack of Hermanric, king of the Franks, and the ravages of this people on the possessions of the Vandals, delayed their departure. Having routed the Suevi in a bloody battle near Augusta Emerita (Merida), Genseric embarked with about 50,000 men, crossed the straits of Gibraltar, and conquered within two years all the cities in Mauritania. When Boniface, repenting of his crime, desired Genseric to return to Spain, he refused and could not be expelled; but he at last agreed in a treaty (435) to be satisfied with Mauritania and Numidia. But the native inhabitants of the Atlas mountains, so long oppressed by the Roman governors, and the Donatists, driven to despair by the persecutions of the orthodox church, joined the standard of Genseric, who soon took up arms again and subdued the province of Africa. In 439 he took Carthage and made it the capital of the Vandal kingdom, which now extended over the whole of North Africa and by piratical expeditions was established in parts of Italy, Sardinia, and Corsica. The invasions of the Huns in the north of the empire made these aggressions on its provinces easier, and it was Genseric who invited Attila to his fatal march on Rome. Rome escaped the hands of the Huns, but fell into those of the Vandals. Invited, as was said, by Eudoxia, widow of Valentinian III., who wanted to avenge the murder of her husband by Maximus, Genseric crossed the straits, sailed up the Tiber, took Rome, and held it for 14 days (June, 455), carried off Eudoxia and her daughters, one of whom he gave to his son Hunneric, and filled the city with treasures and captives to be sent to the shores of the Mediterranean, and from there to Egypt to the straits of Gibraltar, ravaged by the Vandals. A fleet sent by emperor Majorian (457) to check them was destroyed in the bay of Carthage. Another sent by Leo (468) more successful, but repulsed, was victorious until his death. Genseric, of small stature, lame of one leg, lame of one eye, descended from a horse, slow, but very cunning, treacherous, and a skilful ruler. Finally he compelled those who remained faithful to the orthodox faith to leave his kingdom, and the remainder remained treated them as slaves, succeeded by Hunneric.

**GENTIAN**, in medicine, the root of the plant *gentiana lutea*, growing wild in the mountainous portions of Europe, and imported into the United States from Germany. Some other species are also used for medicinal purposes.

*Gentiana lutea.*

One of these, known as the blue gentian (*G. Catesbæi*), is found in the grassy swamps of the Carolinas, and so closely resembles in its properties the officinal gentian, that it is used at the south, and is introduced into the catalogue of the United States pharmacopœia. Its flowers are blue; those of the foreign gentian are yellow, which is also the color of the powdered root. Both have at first a sweetish taste, followed by intense bitterness; and both yield their medicinal qualities to water and alcohol. Its bitter principle, called gentiopierine, is soluble in water and alcohol, and is neither an acid nor an alkaloid, but ranks as a glucoside. The Swiss and Tyrolese macerate the plant in cold water, and the sugar it contains causing it to ferment on standing, they distil from it a spirituous liquor, bitter and unpleasant, but much used by them. As a tonic it has been used from remote times, and the name is said to have been given to it from Gentius, a king of Illyria. It is found as an ingredient in many of the ancient receipts transmitted from the Greeks and Romans. Its effects closely resemble those of the other pure bitters, such as quassia and colombo. In small doses and in suitable cases it increases the appetite, and invigorates digestion. In large doses, or in cases to which it is not adapted, it is liable to disagree with the stomach, exciting nausea and irritating the bowels, and cannot therefore be administered without due reference to the condition of these organs. It is given in powder, in extract, infusion, tincture, or sirup. The powder has been used as an external application to ulcers. In convalescence from fevers and acute diseases, when there is little appetite and a feeble digestion, gentian often increases the former and aids the latter. It is not

well borne when there is any irritation or inflammation of the mucous membrane of the stomach. The tincture contains a large proportion of alcohol, and its physiological and therapeutical value is affected by this ingredient, whose presence should not be forgotten by those who take or administer it. A craving for ardent spirits may be engendered by the long continued use of tincture of gentian and similar tinctures.—Besides the native gentian mentioned above, there are several others found in the Atlantic states, among the most conspicuous of which is the closed gentian, *G. Andrewsii*; the inflated club-shaped blue corolla of this species never opens at the mouth. One of the most beautiful of all wild flowers is the fringed gentian, *G. crinita*, a much-branched annual or biennial species found in low grounds in autumn; the corolla is about two inches long, the tube and its elegantly fringed lobes of a

*Gentiana Andrewsii.*

deep sky-blue. The alpine gentiana, *G. acutella*, *G. verna*, *G. Pyrenaica*, and others, which are among the gems of European flower gardens, are rarely seen in this country, as our soils become too dry in summer to suit their alpine nature.

**GENTILES** (the equivalent of the Heb. *goyim* and Gr. *ethnei*), the name by which the Jews distinguished all other nations or *gentes* from themselves. In its religious bearing it nearly corresponded to our word heathen; for all who were not Jews, and circumcised, they regarded as excluded from all the religious privileges and relations by which they were so greatly exalted. In the writings of St. Paul the gentiles are generally denoted as Greeks. The court of the gentiles about the temple was the outer space, marked off by a wall or balustrade breast high, within which strangers were forbidden to enter, though they might come as far as the barrier to present their offerings. This explains the meaning of Paul,

when he speaks of "the middle wall of partition" between Jews and gentiles as being broken down by the gospel.

**GENTILESCHI, Orazio**, an Italian painter, whose family name was Lomi, born in Pisa in 1563, died in London, or according to some authorities in Rome, about 1646. At the invitation of Charles I. he took up his residence at the court of England, and decorated the palace at Greenwich and other buildings. Vandyke included him in his portraits of 100 illustrious men.

**GENTRY**, a N. W. county of Missouri, intersected by Grand river and drained by its E. and W. forks; area, about 500 sq. m.; pop. in 1870, 11,607, of whom 56 were colored. The chief productions in 1870 were 61,765 bushels of wheat, 640,951 of Indian corn, 135,555 of oats, 44,929 of potatoes, 177,834 lbs. of butter, 52,641 of wool, and 11,082 tons of hay. There were 5,516 horses, 4,014 milch cows, 7,553 other cattle, 18,756 sheep, and 20,585 swine; 3 flour mills, 14 saw mills, and a woollen factory. Capital, Albany.

**GENTZ, Friedrich von**, a German diplomatist and publicist, born in Breslau in 1764, died in Vienna, June 9, 1832. He was considered a dunce until, in his 21st year, he attended Kant's lectures at Königsberg, when his mind was awakened, and he became familiar with the Greek and Roman classics, and mastered French and English. Returning to Berlin, where he had previously studied, he became a favorite in the highest circles, and commenced a career of gallantry, adventure, and authorship. In 1793 he published a translation into German of Burke's "Essay on the French Revolution," with copious notes. In 1794 he translated and annotated Mallet du Pau's book on the same subject, and in 1795 Mounier's. In 1799 he visited England, and for 20 years he was in correspondence with leading members of the British ministries, for whom he drew up many papers on taxation and finance. In 1802 he visited Vienna, and on Sept. 6 of that year was engaged by the emperor Francis as a councillor. He was sent to England to negotiate an alliance, and drew up the Austrian manifesto of 1805. Gentz was furiously assailed in Napoleon's bulletins, and as the court of Vienna was fearful of being compromised by his further presence, he was directed to leave the capital, and for a time he used his skilful pen in combating Napoleon in Prussia. He was recalled to Vienna by Metternich in 1809, wrote the Austrian manifesto of that year, and subsequently proved himself merely the tool of his employer. He took an active part in the congress of Vienna, assisted in framing the treaty of the holy alliance, and acted as secretary at the congresses of Aix-la-Chapelle, Troppau, Laybach, and Verona. He wasted his talents in sophistical pleas for reaction and political quietism, and his means in extravagance and dissipation. His diaries were found among the literary remains of Varnhagen von Ense and published in 1861 (complete ed., 2 vols.,

Leipsic, 1874). His *Briefe an Pilat*, a contribution to recent German history, was edited by Karl Mendelssohn-Bartholdy, with a biographical notice (2 vols., Leipsic, 1868).

**GENUS**, a closely allied group of animals or plants, characterized by ultimate structural peculiarities. Great confusion prevails among describers in the formation of genera from their considering form and complication of structure as generic characters, whereas the former is characteristic of families, and the latter of orders; hence generic, family, and ordinal characters are mixed up in the determinations of almost all naturalists from Linnaeus to the present time, and genera have been unnecessarily and absurdly multiplied. Genera are subdivisions of families, and species are subdivisions of genera; the former, as has been stated, are limited by ultimate structural peculiarities, while the latter bear a closer relation to each other and to their special location, their existence being also confined within a definite period. Generic peculiarities extend to the most minute details of structure of teeth, hair, scales, cerebral convolutions, distribution of vessels, arrangement of intestinal folds and appendages, and microscopic anatomy of the organs; so complete is this identity of structure that (in the words of Agassiz, "Essay on classification," part i., chap. 1) if an animal "submitted to the investigation of a anatomist, after having been mutilated to an extent that none of its specific characters could be recognized, yet not only its order, or its family, but even its genus could be identified as precisely as if it were well preserved in all its parts." Example of the genus *vulpes* (fox), for example, the same dental formula, toes and claws, and generic characters, whether an American, European, or Asiatic, or of its habitat. Genera may or may not differ from each other in form; they may differ in geographical range, and are distinguished by their characters by physical and geographical characters. The generic distinction of *nata* or tortoises, both land and sea, is distinguished principally on the character of the jaw, skin, and feet (see *History of the United States*, vol. i.). An admirable idea of what constitutes a genus is distinguished from families and orders.

**GEODE**, a hollow shell of quartz, found in various localities, lined with crystals of various colors. These crystals are for the most part often amethystine. In the trap are found greenish, yellow, and red, and in the granite, the alluvial, and in the sandstone, of these various colors. Besides quartz crystals, analcime, &c., are found in geodes. Some of the most beautiful specimens of this kind in the world are found in the low stages of water in the upper Mississippi river.

rough and unsightly, of light brown color, and of all sizes up to 12 or 15 inches in diameter; when broken they present beautiful groups of quartz crystals. Water is sometimes found in the geodes holding the silex in solution, and making with it a milky-looking mixture. As the water evaporates the silex has been known to suddenly form into delicate crystals. Such geodes were at one time abundantly found on Brier creek in Scriven or Burke co., Ga., in a rock composed of hornstone and jasper; the milky fluid contained in them was used by the inhabitants as a paint or whitewash. ("American Journal of Science," vol. viii., p. 286.)

**GEODESY** (Gr. *γη*, earth, and *δαιρεω*, to divide), the science and art of laying out divisions of the earth's surface upon a large scale. It differs from ordinary surveying in its measurements, being constantly referred to the spherical surface upon which they are made, and reduced to the same horizontal level. Corrections also are made for horizontal parallax in computing the value of instrumental observations, and the calculus of probabilities is applied to resolve their differences. Its object may even be the determination of the spherical curvature of portions of the surface, which is accomplished by the aid of extended series of astronomical observations made in connection with the most exact measurements. The methods of conducting these operations, and contending with the numerous causes of error incident to the imperfection of the instruments and powers employed, are treated in the article **COAST SURVEY**. The most important results in regard to the figure and dimensions of the earth, deduced from a comparison of the most extensive and accurate geodetical surveys, are given in the articles **EARTH** and **DEGREE**.

**GEOFFREY OF MONMOUTH**, an old English chronicler, born about 1100, died about 1154. He is supposed to have received his education in the Benedictine monastery near Monmouth, where he compiled his *Chronicon sive Historia Britonum*, to which he probably owed his promotion in 1152 to the see of St. Asaph. Geoffrey's chronicle professes to be a translation from an old Welsh manuscript which one Walter Calenius, an archdeacon of Oxford, discovered in Brittany, and which he requested him to render into Latin. That some part of the work is a translation there seems to be no doubt, as its main features agree with the history of Nennius, written several centuries previous; but so numerous are the legends and fables interwoven into it, and so extensive is the period it embraces (from Brut, the great-grandson of Æneas, to the death of Cadwallader or Ceadwalla, king of Wessex, in 688), that its historical value is very inconsiderable. If historians are inclined to doubt the veracity of Geoffrey, the readers of romance are indebted to him for having preserved and perhaps reconstructed the legends of Arthur and his knights. The work was originally divided into eight books, to which Geoffrey added the book

of Merlin's "Prophecies," and was first printed at Paris in 1508. The best recent editions are those of J. A. Giles (1842) and Bohn (1848), both of which are reprints from a translation by Aaron Thompson published in 1718.

**GEOFFRIN, Marie Thérèse**, a French lady, born in Paris, June 2, 1699, died there in October, 1777. Her father, M. Rodet, was in the service of the dauphiness. She was barely 15 when she married M. Geoffrin, a manufacturer, who was ridiculed on account of his mental inferiority to his wife, but whose fortune enabled her to dispense hospitalities to distinguished persons. She became a widow in a few years, and remained to the end of her life one of the most conspicuous leaders of European society. She counted among her friends Diderot, D'Alembert, Horace Walpole, Hume, and Gibbon. Count Stanislas Poniatowski was a constant visitor at her house, and she rescued him from prison by paying his debts. When elected king of Poland in 1764, he said to her, *Maman, votre fils est roi*. On her visiting him at Warsaw in 1766, the leading members of the Polish nobility came to meet her on the road, and the king had a residence prepared for her. Passing through Vienna, she was received with great distinction by the empress Maria Theresa and her son Joseph II. She was unceasing in her assistance to literary men, especially to those connected with the *Encyclopédie*, toward the publication of which she is said to have contributed more than 100,000 francs. Though intimately associated with philosophers and free thinkers, she was somewhat of a devotee, and her daughter, who became the wife of the marquis de la Ferté-Imbault, attempted to wean her altogether from intercourse with her former friends. But it was only during the last year of her life that she was prevailed upon to deny her society to the encyclopædists. Morellet published in 1812 *Éloges de Madame Geoffrin*, comprising his eulogy of her and those by D'Alembert and Thomas, and several of her letters.

**GEOFFROY SAINT-HILAIRE**. I. Étienne, a French zoölogist, born in Étampes, April 15, 1772, died in Paris, June 19, 1844. He was educated for an ecclesiastical life, but evinced a taste for natural philosophy, and had gained some proficiency as a mineralogist when the revolution broke out. Having been incarcerated as a recusant priest, his pupil managed to procure his liberation, and at the peril of his life he rescued 12 other priests from prison, on the very eve of the massacre of September, 1792. A few months later he was appointed to a subordinate office in the *jardin des plantes*, and in 1793, on the reorganization of this establishment under the name of museum of natural history, he was made professor of zoölogy. Through his exertions, the old specimens were put in order, new ones were procured, and the zoölogical collections became the richest in the world. In 1795 he welcomed to Paris George Cuvier, then entirely unknown

to fame. In concert they pursued researches in comparative anatomy, and at that time each of them had but a faint conception of the opposite systems upon which they were to separate 35 years later. In 1798 Geoffroy was one of the scientific commission that accompanied Bonaparte to Egypt; remaining there until the surrender of Alexandria in 1801, he was one of the founders and most active members of the Egyptian institute, thoroughly explored the country, gathered valuable collections of natural specimens, and carried them to France. The papers in which he described these specimens attracted general attention, and resulted in his election to the academy of sciences in 1807. In 1809 he was appointed professor of zoölogy in the faculty of science at Paris, which post he filled for years simultaneously with that at the museum. From 1812 to 1815 his scientific occupations were partly interrupted by sickness and political activity. He was a member of the chamber of deputies during the hundred days; but on the second restoration he returned to his wonted pursuits. He applied himself to demonstrating the principle of which Buffon and Goethe had had but a glimpse, the unity of organic composition among the various kinds of animals; and he founded what he called the "theory of analogues." The unity of composition, according to his idea, is the law of identity in the materials composing the organs of animals of different families, and which, although infinitely varying in shape, bulk, and use, are still the same in all, and discover a single plan; while the theory of analogues is the method through which the unity of composition is demonstrated. As to the unequal sizes among the various creatures, and monstrosities in individuals, they are explained by the principle of arrest of development. These principles, at once bold and original, were in direct contradiction to those which Cuvier had adopted as the basis of his comparative anatomy; and this opposition, which had been silently going on for years, at last broke out openly, July, 1830, in the sittings of the academy of sciences. The contest between the two illustrious champions caused a deep sensation throughout the scientific world of Europe. Notwithstanding the superiority of Cuvier as an orator and scientific expounder, the victory was left undecided, and many among the learned sided with Geoffroy, whom Goethe hailed as an apostle of the true synthetic doctrine. Whatever may have been his faults, he is incontrovertibly, after Cuvier, one of the most important contributors to the advancement of the science and philosophy of natural history. His views contain much of the transcendental element of the German physio-philosophers, and, if carried to their legitimate conclusions, lead to doctrines directly opposed to the prevalent philosophy of final causes. (See PHILOSOPHICAL ANATOMY.) Among his numerous works and papers, which embrace nearly all branches of zoölogy, we

refer specially to the following: *Philosophie anatomique* (2 vols. 8vo, 1818-'22), which contains the exposition of his doctrine; *Principes de la philosophie zoologique* (8vo, 1830), which gives a synopsis of his discussions with Cuvier; *Études progressives d'un naturaliste* (4to, 1835); *Notions synthétiques de philosophie naturelle* (8vo, 1838); *Fragments biographiques* (8vo, 1838); *Histoire naturelle des mammifères*, in conjunction with Frédéric Cuvier (fol., 1831-'42). He also contributed to several great publications, and especially to the description of Egypt by the scientific commission of which he was a member. It was not till 1840 that he gave up active life on account of blindness; a few months later he had a stroke of paralysis; but he withstood his last sufferings with admirable equanimity. His eulogy was delivered by M. Flourens in 1852 at the academy of sciences. An excellent biography had previously published by his son under the title *Vie, travaux et doctrine scientifique d'Étienne Geoffroy Saint-Hilaire* (Paris, 1847). **GEORGE SAINT-HILAIRE**, a French zoölogist, son of the preceding, born in Paris, Dec. 16, 1805, died there, Nov. 10, 1861. Under the direction of his father he devoted himself to natural philosophy, and came assistant naturalist at the museum only 19 years old, and in 1830 delivered public lectures in that institution as a substitute. Three years later he was elected to the academy of sciences. He was publishing a great work in which he treated upon a branch of the natural system by his father; this was his *Histoire générale et particulière des anomalies de l'organisation chez l'homme et les animaux, ou traité de tératologie* (3 vols. 8vo, with an atlas). On its completion he was appointed lecturer to his father at the faculty of medicine, afterward filled some important positions at the university, and in 1850 resigned to become general inspector to resume the chair of zoölogy. He devoted his leisure to his *Histoire générale des règnes organiques*, of which two volumes were published (1855). He also paid much attention to the natural history of foreign animals in France, and his treatise *Domestication des animaux utiles* (1856), on the use of horse flesh as food, and *substances alimentaires, et la viande de cheval* (1856).

**GEOGRAPHY** (Gr. *gē*, the earth, *graphein*, to write), the description of the earth. The science comprises three parts: mathematical, physical, and political. Mathematical geography treats of the figure, extent, and position of the earth; of the celestial globe, and of the solution of problems, of the position of places on the surface, and of representing that surface on maps or charts. (See ASTRONOMY,

cal geography treats of the earth and its features of land, water, and air, its animal and vegetable inhabitants, without reference to national or political divisions. (See PHYSICAL GEOGRAPHY.) Political geography describes the countries and nations of the earth as they are politically divided, and deals with mankind in their social aspect and organization. The details of this branch of the science will be found under the names of the various countries, cities, and towns. The Phœnicians were the first who made any great progress in extending the bounds of geographical knowledge. They explored all the coasts of the Mediterranean, and at an early period passed the strait of Gibraltar, and visited the Atlantic shores of Europe and Africa, extending their voyages northward and northeastward as far as Britain and the Baltic coasts, and southward to the tropic of Capricorn. Their neighbors, the Hebrews, probably acquired from them some knowledge of distant lands. In the Scriptures the remotest regions mentioned are, to the north, Gomer (Gen. x.), which probably designated the Kimmerii of Herodotus, and Kir, the Caucasian region of the Kur; to the east, India (Esther i. 1), and very probably China, called the distant "land of Sinim" (Isaiah xlix. 12); to the south, Cush (Ethiopia), Ludim or Lubim (Libya), Dedan (on the Persian gulf), Sheba (S. W. Arabia), and Ophir, concerning whose situation many conjectures have been made, the most probable of which seems to be that it was in southern Asia. To the west, the extreme land was Tarshish, which was probably Tartessus in Spain, though various other identifications have been attempted by critics. The first attempt to enlarge the bounds of geographical knowledge by an exploring expedition was made by Necho, king of Egypt, shortly before 600 B. C. He sent down the Red sea into the Indian ocean a fleet manned by Phœnicians, which in the third year, after circumnavigating Africa, reached the pillars of Hercules or strait of Gibraltar, and returned to Egypt by the Mediterranean. The Phœnicians asserted that during a part of the voyage the sun was in the north. This statement, which shows conclusively that they must have sailed to the south of the equator, Herodotus, naturally enough, wholly discredited. The geographical knowledge of the ancients was greatly enlarged by the Carthaginians, whose extended commerce led necessarily to long voyages, but the only authentic account of any of their maritime expeditions which has reached us is that of Hanno, the time of which is uncertain, but is plausibly conjectured to have been in the 5th century B. C. With 60 vessels he passed the strait of Gibraltar, and sailed down the coast of Africa, as some writers suppose, to the gulf of Benin, while according to others he proceeded no further than the river Nun. About 320 B. C., Pytheas, a seaman of Massilia, the modern Marseilles, sailed out into the

Atlantic, coasted the shores of Spain and Gaul, visited Britain, and passing onward discovered an island, which from that time was famous among the ancients as *Ultima Thule*. Some modern geographers have conjectured that this was Iceland, others that it was Jutland, and others that it was Shetland; but nothing certain is known about it. In a second voyage he passed into the Baltic. The expedition of Alexander the Great, 330 B. C., greatly enlarged the knowledge of India. He penetrated to the Hyphasis, the modern Sutlej. The ambassadors of Seleucus, one of his successors, reached the Ganges and visited the city of Palinibothra, which was probably on or near the site of the modern Allahabad. Beyond this the Greeks seem to have known little or nothing of eastern Asia. The first systematic attempt at scientific geography was made by Eratosthenes, who flourished at Alexandria in the latter part of the 3d century B. C. The globular form of the earth was at this time known to the scientific schools of Alexandria, and the system of Eratosthenes was based upon its recognition, though he disregarded the great primal features of modern geographical science, the equator, the poles, and the tropics. The base line of his geography was a parallel drawn through all the places where it was supposed that the longest day was 14½ hours. It stretched from Cape St. Vincent in Spain eastward through Rhodes, Asia Minor, Persia, and India, till it terminated at the city of Thina, which was supposed to be on the shores of the eastern ocean, at the utmost extremity of the earth. The length of this line, according to Eratosthenes, was about 70,000 stadia, or a little more than 8,000 English miles. At right angles to this Eratosthenes traced a meridian which passed through Rhodes and Alexandria southward, through Syene and Meroë, till it reached what was supposed to be the uninhabitable region, the northern bounds of which were fixed at 12 degrees from the equator. Thule was regarded by Eratosthenes as the extreme northern end of the earth, and the distance from there to the habitable limit toward the equator was computed at 38,000 stadia, or nearly 4,400 miles. Beyond these limits it was commonly supposed that nothing existed but an impassable ocean, though Eratosthenes cautiously conjectures that continents and islands might be reached by sailing westward. Hipparchus, a Bithynian who lived at Rhodes and Alexandria about the middle of the 2d century B. C., carried still further the system adopted by Eratosthenes, and subjected the whole science of geography to astronomical principles. He made numerous observations of latitude in addition to the few previously existing, and pointed out the mode in which longitudes might be ascertained by observing the eclipses of the sun and moon. But his discoveries were neither appreciated nor applied to any practical use till long after his time. About a century and a half after

Hipparchus, Strabo, a Greek of Pontus and a great traveller, wrote a geography which embodied all that was known of the science at the beginning of the Christian era. The countries immediately around the Mediterranean were known with tolerable accuracy; but the Atlantic shores of Europe were very erroneously comprehended, while of the northern and eastern portions only the vaguest ideas were entertained. Nothing whatever was positively known of Scandinavia, Russia, or northern Germany. The extent of Europe to the east and northeast was greatly exaggerated, while that of Asia was proportionally underrated. Nothing was known of Siberia, Tartary, China, Japan, or the great Asiatic archipelago. The Ganges was thought to have throughout an easterly course, and to flow into the eastern ocean. The Caspian was supposed to be the limit of the earth to the north, and to be connected with the eastern ocean by a sea occupying the space now known to be covered by Siberia and Tartary. Of Africa only the northern part was known, south of which was thought to be an uninhabited and uninhabitable torrid zone. The belief in the probability of circumnavigating Africa, which had existed in previous ages, was rejected by Strabo, though he held to the theory of an encircling ocean. The earliest Roman geographer was Pomponius Mela, who wrote about the time of the emperor Claudius. In his treatise *De Situ Orbis* he explains the division of the world into two hemispheres: the northern that part of the earth which is known, the southern that which is unknown. The former is divided into three great divisions, Europe including all N. of the Mediterranean and W. of the Tanais, Africa all S. of the Mediterranean and W. of the Nile, and Asia all the remainder. A still more famous geographer was Ptolemy, who lived at Alexandria about the middle of the 2d century after Christ. At this period the Roman empire had reached its greatest extent, and all its provinces had been surveyed and were well known. Large advances had been made in the knowledge of the countries outside of the empire. The notion of a circumambient ocean had been given up, and an indefinite expanse of *terra incognita* substituted as the supposed boundary of the world. Africa was represented as stretching indefinitely south, and it was even carried round to join the east of Asia, so that the Indian ocean was enclosed like the Mediterranean. In Europe, Spain and Gaul were for the first time correctly delineated, together with the southern part of Britain. The outline of Scotland and the relative position of Ireland are very incorrectly given. Thule is laid down as an island upward of 100 m. long. From its position it is probable that some part of Norway was meant. Northern Germany and the southern line of the Baltic coast were tolerably well known, as was also some portion of Russia in the neighborhood of the

Baltic and the southern part of Russia in Europe. In Asia, great regions had become known sufficiently to make it certain that they were inhabited by nomad tribes called Scythians, while from the far east some vague report of China and of the regions now known as Chin-India had reached the geographer. From the time of Ptolemy till the revival of letters in Europe little progress was made in geographical knowledge. In the 9th century, however, the Northmen discovered Greenland, and in the 10th, according to their sagas, visited the North American continent. In the 13th century missions were sent by the popes into remote parts of Asia. Father John de Plano Carpini, with some Franciscan monks, was sent in 1246 by Innocent IV. to Kayuk Khan, the Tartar emperor, and penetrated as far as Tibet. In 1253 Rubruquis, another Franciscan, was sent by Louis IX. of France in search of Prester John, and penetrated further into Asia than any European ever had before. But the greatest discoveries in this quarter were made by Marco Polo, a Venetian, who in 1271 set out with his father and uncle on a journey to the court of Kublai Khan, the Tartar conqueror of China. After travelling for more than three years they reached Yehking, now where Peking now stands. Marco Polo resided 24 years in the East, and on his return gave an account of his travels, which first made known to Europe the existence of Japan and many of the East Indian islands and countries. In the 15th century the spirit of enterprise and geographical exploration was strongly aroused in Europe. Portugal took the lead, and made great and systematic efforts to explore the unknown countries on the W. coast of Africa. In the year 1413 Cape Nun was doubled, and soon afterward the islands of Porto Santo and Madeira were discovered. In 1484 Benin and Congo were discovered, and the coast explored for 1,500 m. S. of the equator. In 1486 the cape of Good Hope was reached, and 11 years later doubled by Vasco da Gama. But the greatest of geographical discoveries was that of the world by Christopher Columbus. From this time forward the progress of geographical exploration was exceedingly rapid. Within 30 years from the date of the voyage of Columbus the whole E. coast of Africa from Greenland to Cape Horn had been explored, and Spanish keels were flowing into the Pacific ocean. In 1520 Magalhaens discovered the strait which bears his name, crossed the Pacific, and although he was killed on the Philippine islands, his vessel, crossing the Indian ocean, returned to Europe by the cape of Good Hope, having been the first to circumnavigate the globe. The discovery of America, with the exception of the N. of the bay of San Francisco, was made before the middle of the 15th century. A considerable progress was made by the Spaniards in acquiring a knowledge of

South America. At the same time discovery in the East advanced with rapid strides. Within 20 years from the time of Gama's arrival in India, the coasts of E. Africa, Arabia, Persia, Hindostan, and Further India had been explored, and many of the islands of the great archipelago discovered. In the 16th and 17th centuries the progress of astronomical science led to a general revision of Ptolemy's tables of latitude and longitude, which had for ages been received with implicit confidence, but which more accurate observations now proved to be generally erroneous. In the 18th century many learned and laborious writers, among whom D'Anville may be particularly mentioned, applied themselves to the rectification of the whole system of ancient geography, and to the identification of ancient with modern countries, cities, rivers, mountains, and other features. The desire to discover a shorter route to India than those by Cape Horn and the cape of Good Hope led the English and the Dutch in the 16th century to make daring and persevering efforts to effect a N. E. and a N. W. passage. For a long time the opinion prevailed that the northern extremity of America terminated, like the southern, in a point or cape, by sailing around which the mariner could enter the Pacific ocean and make his way to India. The expeditions of Sir Hugh Willoughby and Richard Chancellor in 1553, of Frobisher in 1576-'8, of Davis in 1585-'7, of Barentz in 1594-'6, in search of this northern route, greatly enlarged the knowledge of the arctic regions, and especially of the N. E. part of North America. So, too, in the succeeding century, a similar result followed from the voyages of Henry Hudson in 1607-'11, and of William Baffin in 1612-'16. It was not till the latter part of the 18th century, however, that the great breadth of the upper part of North America became fully known from the investigations of Capt. Cook in his voyages to the Pacific. The determination of the distance from Behring strait to the E. coast of North America dispelled for a time all expectation of a N. W. passage; it was supposed that the continent stretched in one unbroken mass to the pole. The discoveries of Hearne in 1771 and of Mackenzie in 1789, by showing that an ocean bounded America on the north, dispelled these ideas, and in 1818 the attempt to effect the N. W. passage was revived by an expedition commanded by Capt. Ross. This was the beginning of a series of English and American expeditions to the arctic regions which have greatly advanced our knowledge of that part of the world, though without attaining the object for which they were commenced. (See ARCTIC DISCOVERY.) Early in the 17th century the Dutch, while seeking for a southern continent whose existence was supposed necessary to balance the northern, discovered Australia, which they called New Holland, and explored a considerable portion of its coasts. In 1642

Tasman discovered Van Diemen's Land, or Tasmania, as it is now called. Soon afterward he discovered New Zealand and several of the Polynesian groups. His explorations proved that New Holland was an island, and not a part of the southern continent. The famous Capt. Cook in his voyages, 1768-'79, made strenuous efforts, without success, to discover the southern continent; but he added largely to geographical knowledge by his survey of the Pacific ocean and its innumerable islands. An expedition sent out by the United States in 1838, under command of Lieut. Wilkes, in 1842 discovered a continent within the antarctic circle, portions of which had been seen shortly before by the French and English navigators Dumont d'Urville and Sir James Ross. (See ANTARCTIC DISCOVERY.) Our acquaintance with the interior of Asia has been greatly advanced within the last two centuries by Russian, English, and French conquests, and by a multitude of travellers, prominent among whom have been the Jesuit missionaries, so that our general knowledge of that continent is tolerably complete. No great *terra incognita* remains, though fuller and more precise information about the vast regions known as Tartary is much to be desired. The travels of Humboldt, of Lewis and Clarke, and of Fremont have enlarged our acquaintance with the interior of the American continent; and during the last few years much light has been thrown upon it by the various exploring expeditions sent out by the government, and especially by companies of professors and students from our colleges. The interiors of Australia and of Africa are still only partially known. Much has been done for the exploration of the former by Sturt, Eyre, Leichardt, Stuart, McKinlay, Landsborough, Burke, the brothers Gregory, and others; while in Africa a host of travellers have struggled for a century past to penetrate the mystery which envelops that great division of the globe. Foremost among the African explorers have been James Bruce, Mungo Park, Major Denham, Lieut. Clapperton, Richard Lander, Captains Burton and Speke, Dr. Livingstone, Dr. Barth, Heuglin, and Sir Samuel Baker. Great additions to our knowledge of the countries on the upper Nile have been made by expeditions sent by the pasha of Egypt, which have penetrated far beyond the region so long assigned on our maps to the mountains of the Moon. These expeditions and the researches of Barth, Burton, Livingstone, Baker, and the missionaries Rebmann and Krapf, have left in obscurity only a portion of that part of Africa which lies between lat. 10° N. and 10° S., and lon. 12° and 27° E. Dr. Livingstone at the time of his death was endeavoring to penetrate this region.—The remarkable progress of geographical discovery during the present century may be thus briefly summed up: Northern Asia has been traversed by the expeditions sent out by the Russian government; the great fields

of central Asia have been crossed in various directions; our knowledge of China has been vastly increased; the newly awakened desire of the Japanese to participate in the advantages of European civilization has broken down much of their ancient prejudice against foreigners, and bids fair to introduce us to an intimate and exact knowledge of their country; Palestine has been explored with wonderful minuteness; the interior of Arabia has been penetrated; the sites of many of the most renowned cities of antiquity have been determined; the Niger and the Benooe or Tchadda have been traced almost throughout their extent; the Nile has been traced to the great lakes in the equatorial regions of Africa; Madagascar and Australia have been crossed in various directions from sea to sea; the icy continent about the south pole has been discovered; the delineation of the N. shore of the North American continent has been completed; the principal features of the geography of that vast portion of our own territory lying between the Mississippi and the Pacific have been ascertained, and its sublime scenery has been described; and the river systems of South America have been explored. With the exception of the regions about the poles and in the centre of Africa, the general outlines of every part of the earth's surface are known to civilized man.—The literature of geography, to which the school of Carl Ritter has given its highest degree of scientific development, has within a few years undergone a marked change. Instead of the formal, regular descriptions of the earth and its inhabitants, which were once in vogue, gazetteers and geographical dictionaries are now popular. The progress of geography has been much aided during this century by the efforts of zealous geographical societies. Their transactions, issued periodically, contain a vast and constantly increasing mass of information. Among the best works on geography are: *Géographie universelle*, by Malte-Brun (6 vols. 8vo, Paris, 1810-'29; revised by Th. Lavallée, 6 vols. 8vo, 1856-'62), the English translation of which was revised by J. G. Percival, who added notes (3 vols. 4to, Boston, 1834); *Die Geschichte der Erdkunde*, by Lüdde (1840); *Geschichte der Erdkunde und Entdeckungen*, by Carl Ritter (1861); *Geschichte der Erdkunde bis auf Alexander von Humboldt und Carl Ritter*, by O. Peschel (1865); and the works of De Rougemont, Von Roon, Berg-haus, Volger, Merleker, Meinicke, Klöden (*Handbuch der Erdkunde*, 1858-'62; 2d ed., 1865 et seq.), Wappäus (*Handbuch der Geographie und Statistik*, 4 vols., 1855-'71), and Daniel (*Handbuch der Erdkunde*, 4 vols., 3d ed., 1869-'72). For ancient geography, see *Handbuch der alten Geographie*, by Forbiger (3 vols., 1842); Smith's "Dictionary of Greek and Roman Geography" (2 vols. 8vo, London, 1854-'7); Buchholz's *Homerische Kosmographie und Geographie* (1871); and *Deutsche Alterthumskunde: Stellung des Pytheas* . . .

*in der Geschichte der Erdkunde*, by K. Mül-lhoff (1870). The principal geographical gazetteers and dictionaries are: "Encyclopædia of Geography," by Hugh Murray (London, 1834; Amer. ed. revised, 3 vols. 8vo, Philadelphia, 1843; new ed., 1857); "A Dictionary. Geographical, Statistical, Historical," &c., by J. E. McCulloch (4 vols. 8vo, London, 1841; new ed. 1866); Fullarton's "Gazetteer of the World" (7 vols. 8vo, Edinburgh, 1850-'57); "The Imperial Gazetteer," by W. G. Blackie (2 vols. London, 1855; 3d ed., 1873); Ritter's *Geographisch-statistisches Lexikon* (Leipzig, 1855); Lippincott's "Gazetteer of the World" (Philadelphia, 1855; new ed., 1866); Keith Johnston's "Dictionary of Geography" (revised ed. London, 1867); *Dictionnaire de géographie universelle, ancienne et moderne*, by L. N. Berche-relle (4 vols. 4to, Paris, 1856-'8; new ed., 1865); and *Dictionnaire universel d'histoire et de géographie*, by M. N. Bouillet (1 vol., Paris, 1842; 22d ed., 1871). Most of the geographical societies publish periodicals, the principal of which are those of Paris (*Bulletin*, 1822 et seq.), London ("Journal," 1831 et seq.; "Proceedings," 1855 et seq.), Berlin (*Zeitschrift*, 1840 et seq.), St. Petersburg (1848 et seq.), Geneva (*Journal*, 1861 et seq.), and Florence (*Bollettino*, 1867 et seq.). Other valuable geographical periodicals are Petermann's *Geographische Mittheilungen* (Gotha, 1855 et seq.), and its *Ergänzungshefte* or supplements; Saint-Martin's *L'Année géographique* (Paris, 1863 et seq.); and "Ocean Highways" (London, 1871; new series, 1873 et seq.).

**GEOLOGY** (Gr.  $\gamma\eta$ , the earth, and  $\lambda\omicron\gamma\omicron\varsigma$ , course), the science which treats of the nature of the earth, and of the methods by which its materials have been arranged. The term are confounded two distinct branches of study, the one being that of the physical, and biological laws which have presided over the development of the globe, the other the natural history of the earth as displayed in its physical structure, geology, mineralogy, and palæontology. The name of geognosy, employed by Werner, may be very appropriately reserved for the former, while that of geogeny is reserved for the first or theoretical division of the subject. The knowledge of physical geology, the distribution of land and water on the earth's surface, and of the laws of wind, rain, and climates, is one of the first and most important study of geology. Then comes the study of the various kinds of rocks, their arrangement and structure, their relative antiquity, their chemical and mineral history. The investigation of the natural agencies which have presided over the formation of the various kinds of rocks, and the laws which have regulated their structure, and arrangement, belongs to the physical geology. The study of the life in past time played on the earth's surface, and of the laws which have regulated its development, belongs to the biological geology.

less important than it does to-day, and the study of the organic remains found in the various rocky strata, and known as fossil plants and animals, gives rise to departments of botany and zoölogy which are sometimes called palæobotany and palæozoölogy, but are more generally included under the common term of palæontology. The changes that have taken place in the inorganic and organic world introduce in their study considerations of time and progress, and the science is found to be largely of a historical character; the geologist, as Cuvier remarked, being an antiquary of a new order. Its historical element is regarded by Lyell as so prominent that he defines geology simply as "the science which investigates the successive changes that have taken place in the organic and inorganic kingdoms of nature." In the present article little more will be attempted than to present a general sketch of the history and progress of geological science, a reference to some principal objects of its pursuit, and the system of classifying the groups of rocks generally adopted. The history of the science as developed in Europe is minutely traced in the familiar work of Lyell, "Principles of Geology," in which the whole subject may also be most advantageously studied.—From the earliest times the structure of the earth has been an object of interest to man, not merely on account of the useful materials he obtained from its rocky formations, but also for the curiosity awakened by the strange objects it presented to his notice. The south and west of Asia and much of the country bordering the Mediterranean were particularly favorable for directing attention to geological phenomena. Earthquakes were frequent, changing the relative positions of sea and land; volcanoes were seen in operation, adding layers of molten rock to those of sand and mud filled with the shells of the Mediterranean; the strata in the hills abounded in evidences of similar collections of vestiges of marine life far removed from access of the sea, and yet unchanged during the period of human observation and tradition; the Ganges and the Nile, pouring forth their vast sedimentary accumulations, were plainly building up the deltas at their mouths, and the broad valleys reaching far up their course were unmistakable productions of the same series of operations in remote periods. These phenomena could not escape the attention of the philosophers among the ancient Egyptians and Indian races; and their influence is perceived in the strange mixtures of correct observation and extravagant conceit which make up their cosmogonies or universal theories of the creation. In the first chapter of the ordinances of Manu alternating periods of destruction and of renovation are distinctly recognized, extending in eternal succession throughout the whole assemblage of locomotive and immovable creatures, each period comprehending a duration of many thousand ages. The Greek schools of philosophy rec-

ognized these phenomena, which were clearly enunciated by Ovid in presenting the doctrines of Pythagoras. Remarkably free from extravagant statements, they were applied to prove a system of perpetual change slowly modifying the surface of the earth. Aristotle recognized the interchanges constantly taking place between land and sea by the action of running water and of earthquakes, and remarked how little man, in the short span of his life, can perceive of operations extending through the eternity of time. Strabo distinctly applied the raising up of land, not merely of small tracts, but of continents also, by earthquake convulsions, to account for the perplexing phenomenon of beds of marine shells contained in the interior of hills far distant from the sea. Arabian philosophers of the 10th century are also cited who entertained similar views of the changes going on and their causes.—The Italian philosophers in the early part of the 16th century were the first to engage in systematic investigations concerning the true nature of fossil shells. Their abundance in the strata of the sub-Apennine range could not fail to arrest attention and excite inquiries, which were the more perplexing from the limited time allowed in popular belief to the past duration of the earth, and from the general persuasion that no great catastrophe except the Noachian deluge could have occurred to modify its surface. Various fanciful explanations were therefore adopted in the spirit of the scholastic disputations, and for three centuries argumentations were sustained with much spirit on the questions: first, whether fossil remains had ever belonged to living creatures; and secondly, admitting this, whether all the phenomena could not be explained by the deluge of Noah. Among those distinguished for the soundness of their views in the commencement of this controversy are Leonardo da Vinci, the celebrated painter, who died in 1519, and Fracastoro, whose attention was engaged by the multitude of curious petrifications which were brought to light in 1517 in the mountains of Verona, in quarrying materials for repairing the city. He exposed the absurdities of the theories which referred the petrifications to a certain plastic force in nature that could fashion stones into organic forms, and showed the inadequacy of the traditional deluge to bring together the marine fossils that form solid strata of the earth. About this time collections of these curiosities were made for public museums and private cabinets; they were deposited in the museum of the Vatican at Rome, and that of Canceolarius at Verona became famous for them. Descriptive catalogues of these collections were published; and as early as 1565 appeared one of the collection of J. Keutman in Gesner's work *De Rerum Fossilium, Lapidum et Gemmarum Figuris*. In 1580 Palissy was the first who dared assert in Paris that fossil remains of testacea and fishes had once belonged to marine animals. The truth made but slow progress in the face of

established prejudices. In 1669 Steno, professor of anatomy at Padua, published his work *De Solido intra Solidum naturaliter Contento*, in which he proved the identity of the fossil teeth found in Tuscany with those of living sharks, and the close similarity of the fossil testacea to living species; he traced their progressive change from unaltered shells to solid petrifications, and recognized the distinction between formations deposited by salt and by fresh water, and that some were of an earlier period than the introduction of plants and animals upon the earth. But neither he nor Scilla, the Sicilian painter, who in his Latin treatise on the fossils of Calabria, illustrated by good engravings (1670), ably maintained the organic nature of fossil shells, ventured to refer their occurrence in the strata to any other cause than the Mosaic deluge. Leibnitz, the great mathematician, in his *Protogæa* (1680), first proposed the theory of the earth having originally been a burning luminous mass, which since its creation has been cooling down, and as it cooled received the condensed vapors which now compose its crust. In one stage of its formation he believed it was covered with a universal ocean. From these materials Leibnitz traced two classes of primitive formations, the one by refrigeration from igneous fusion, the other by concretion from aqueous solution. The first recognition of the arrangement of the earthy materials in strata, continuous over large areas, and resembling each other in different countries, appears to have been by Dr. Lister, who sent to the royal society of London in 1683 a proposal for maps of soils or minerals. He also believed that species had in past ages become extinct. Dr. Robert Hooke near the close of the 17th century prepared a "Discourse on Earthquakes," which contains the most philosophical views of the time respecting the nature of fossils and the effects of earthquakes in raising up the bed of the sea. William Woodward was a distinguished observer of the geological formations of Great Britain, and perceived that the lines of outcrop of the strata were parallel with the ranges of the mountains. About 1695 he formed a collection of specimens, which he systematically arranged and bequeathed to the university of Cambridge. For this he purchased the original specimens and drawings of fossil shells, teeth, and corals of Scilla. But his geological system was cramped by the attempt to make it conform to the received interpretation of the Scriptural account of the creation and deluge. The Italian geologists Vallisneri in 1721, Moro in 1740, and Generelli in 1749, advanced the most philosophical views yet presented respecting the fossiliferous strata, and sustained them by original observations made by the first two throughout Italy and among the Alps. Moro endeavored to make the production of strata correspond in time to the account of the creation of the world in six days, and hence was compelled to refer them to volcanic ejections, which by floods, he

imagined, were distributed over the surface of the earth and piled up in strata with marvellous celerity. Buffon advanced views respecting the formation and modification of mountains and valleys by the action of water, in his "Natural History" (1749), a portion of which, contained in fourteen propositions, he was required by the faculty of theology in Paris to renounce. This he did in his next work, accompanying the formal abandonment of what he had written contrary to the narrative of Moses with a declaration of belief of all contained in the Scripture about the creation, both as to order of time and matter of fact.—Geology did not begin to assume the rank of an important science until its application to the practical purposes of mining was first pointed out in the last quarter of the 18th century by Werner, professor of mineralogy in the school of mines at Freiberg in Saxony. This distinguished man attracted pupils from distant countries, and sent them forth enthusiastic geologists and advocates of the views he had conceived from his imperfect observation of the geology of a small portion of Germany. He taught the systematic order of arrangement of the strata, adopting nearly the same divisions that had been proposed fifty years previously by Lehmann, a German miner. He explained their production as the result of precipitation from a common menstruum or "chaotic fluid," which he supposed had once covered the whole surface of the earth. As expounded by Jameson in 1806, the first precipitates from this ocean were chemical, and produced the crystalline rocks which lie at the base of all the others which he designated as the primitive. They included the granitic rocks, called crystalline schists, such as slate, clay slate, serpentine, &c. This class comprised the rocks he calls certain limestones, flinty slate, gneiss, wacke, and trap, most of which are now included in the palæozoic formation. They were supposed to have been formed during the transition of the earth from its chaotic to its habitable state, and were produced by chemical and partly mechanical means, and due to the action of heat and water. The third class contained the rocks nominated *Flötz*, because as observed by many they were disposed in horizontal strata. In this were the sandstones, the chalk, rocks, various limestones, and certain others supposed to have been formed when plants and vegetables existed in the water. They had been partly chemical and partly mechanical in their origin. The fourth class comprised the alluvial rocks, those produced by the action of water, peat, sand and gravel, loess, tuff, &c., being understood as deposited after the chalk excepting the volcanic rocks. The fifth class comprised the volcanic rocks, volcanic, and the true volcanic rocks, being the supposed products of volcanic action.

of coal and sulphurous matters, the latter of real volcanoes. These formations were supposed to be systematically arranged; the later formed either entirely covering the older, or, when these form a central mountain mass, encircling this, so that the "outgoings" of the strata (meaning their upper edges or lines of outcrop) form circles; those of the later formed groups being successively larger. The basin and trough-shaped deposits were also recognized, in which the outgoings of the newer strata became successively smaller. The strata, it was understood, were subject to local disturbances from portions sinking into subterranean cavities, and members might be wanting in some localities, but whenever present must be found in their proper position in relation to the others. Basalt, which in Saxony and Hesse was seen capping the hills of stratified rocks, he inferred must be of the same series of precipitated formations, although many other geologists of Werner's time had fully established the analogy between this rock and modern lavas. The observations of Desmarest, especially in the district of extinct volcanoes in Auvergne, made in 1768, are referred to by Lyell as most clearly tracing the origin of the basalts to the craters of the volcanoes. A new controversy now arose, which for many years was waged with animosity and bitterness unprecedented in disputes of this class. Geologists throughout Europe were divided into the two classes of Neptunists, who advocated the production of the rocks by aqueous deposition alone, and Vulcanists, who attributed the origin of many of them to the action of fire. They were also called, from the names of their respective leaders, Wernerians and Huttonians. Dr. Hutton of Edinburgh had studied geology for himself in different parts of Scotland and England, and formed his own conclusions, which he ably sustained. He was the first to announce that geology had no concern with questions as to the origin of things, but that the true field of its investigations was limited to the observation of phenomena and the application of natural agencies to explain former changes. His friend Sir James Hall showed by actual experiment that the prismatic structure of basalt might result in cooling from a state of igneous fusion; and Hutton himself found in the Grampian hills the granite branching out in veins, which extended from the main body through the contiguous micaceous slates and limestone, thus indicating its having been in a fused state at a time subsequent to the production of Werner's primitive rocks. This discovery soon led to questioning the existence of any primitive class of rocks the origin of which lay beyond the reach of the present order of things; and the announcement made by Hutton, "In the economy of the world I can find no traces of a beginning, no prospect of an end," may well have startled men of science and shocked the religious public in the sensitive condition to which it had been

brought by the infidel doctrines promulgated in the latter part of the last century, especially by men of letters in France. The Vulcanists came to be classed with the enemies of Scripture, the true object of investigation was lost sight of, and the controversy was continued with such animosity that the party names at last became terms of reproach, and many geologists avoided being involved in it. Workers in the field, however, were collecting new and valuable data that were to give to the science a more exact character. William Smith, a civil engineer, prepared in 1798 a tabular view of the strata near Bath, tracing out their continuity over extensive areas, and recognizing them by the fossils they contained. This method of identification and of arranging strata in their true positions he taught himself, and was the first to promulgate in England. With extraordinary perseverance he continued to prosecute his work alone, travelling on foot over all England, freely communicating his observations, and in 1815 he completed a geological map of the whole country. In France the importance of fossils as characteristic of formations was also beginning to be appreciated. Lamarck and DeFrance earnestly engaged in the study of fossil shells, and the former in 1802 reconstructed the system of conchology to introduce into it the new species collected by the latter in the strata underlying the city of Paris. Six years previous to this Cuvier had established the different specific character of fossil and living elephants, which opened to him, as he said, views entirely new respecting the theory of the earth, and determined him to devote himself to the researches which occupied the remainder of his life. In 1807 the geological society of London was established, with the professed object of encouraging the collection of data, multiplying and recording observations, with no reference to any "theories of the earth." Its active members completed the classification and description of the secondary formations of Great Britain, so well commenced by William Smith; while at the same time the tertiary formations were thoroughly investigated by Cuvier, Brongniart, and others in Paris. Thus each country contributed to the advancement of geological science in the department connected with its most prominent formations: Germany in that of the lower stratified and crystalline rocks, and especially in the mineralogical structure of these, while in Scotland the character of the granitic rocks had been more particularly elucidated, in England that of the secondary strata and their order of arrangement, and in France the tertiary. The great principles gradually developed by these observations were: that the materials of the stratified rocks were sedimentary deposits that had slowly accumulated in the beds of ancient seas and lakes; that each stratum represented a certain period during which its materials were gathered, and that this period was characterized by its peculiar group of organized beings, the

vestiges of which were buried and remained with it as records of the condition of this portion of the earth during this time. The piles of strata of various kinds indicated changes in the character of the deposits introduced, sandstones formed from sand, alternating with shales formed from muddy and clayey deposits, and with calcareous strata, whose origin may have been in marl beds or the remains of calcareous organisms. The long succession of these strata, in connection with the evidences of their slow accumulation, observed in the undisturbed condition of the fossil remains which they contained, bore witness to long periods occupied in the production of a single group of strata constituting but a minor division of one of the formations. The lapse of long periods was also indicated by the fossils found in beds of older date becoming constantly more and more unlike existing species. The same localities, too, presented in their successive beds some that were filled with marine vestiges alone, corallines and sea shells, in layers of such thickness that ages must have passed while they were quietly accumulating; and above or below these were found other strata indicating that the surface at another period was covered with fresh water, the organic remains which they contained being only of the character of those belonging to ponds and rivers; and yet again these localities became dry land, and were covered with the forests of tropical climes, and peopled with numerous strange species of animals, whose nearest living analogues are met with only in hot countries. Such changes as these also plainly marked slowly progressing revolutions, the period of which no one could compute by years. It was apparent that the sediments had collected as beds of sand and clay now collect in seas and lakes, and especially about the mouths of large rivers; but it was only in such as were evidently the product of the streams of the present day that the organic vestiges were recognized as belonging entirely to familiar species. In these alone were discovered any relics of man or any indications of his existence; and here they were not wanting, for in the calcareous strata in process of formation and filled with recent species of shells human remains have been found. But with the first step backward the bones of extinct gigantic mammalia introduce us to strange groups of animals, and no satisfactory evidence is afforded, either in the strata or in tradition, that man was their contemporary. Thus in the closest connection, geologically speaking, are we presented with the most striking examples of other great principles developed by geological research, viz., the extinction of old and the introduction of new species.—In consequence of the system of observation and close investigation now established, geology lost its highly speculative character, and rapid progress continued to be made in acquiring correct information of the arrangement of the strata of different coun-

tries. While the defects of Werner's classification were exposed, the general plan of it was seen to be founded in nature, and attention was directed to collecting everywhere the materials for filling out the vertical column of the rocks, as well as mapping them throughout their horizontal range. In every country some formations could be recognized from which as a base a local classification might proceed to contiguous groups, and thus at last the whole be included in one system of classification. So the work of descriptive geology has ever since been going on, new discoveries continually adding to its completeness and helping to the compilation of a perfect system, which in this case should present a full chart of the rocks from the lowest or oldest to the uppermost or newest. Strata lying in juxtaposition in one region, when identified in another, are found to be separated by the interpolation of a new series; and again, in tracing out over broad areas a group of sedimentary strata, they are found gradually to assume new features, and even to undergo an entire change of chemical composition. The deposits over different parts of the ocean's bed are found to be here sand and gravels brought by currents, and there soft calcareous muds, the remains of minute animal organisms accumulated in still waters. The organic remains as well as the mineral character of these contemporary deposits present wide differences. From the mode of their formation it is evident that all stratified formations must be of limited area, and in away at their edges, presenting the sun-like lenticular sheets lapping upon each other. In 1819 the geological society of London began the labors of Mr. Greenough and his associates, who published a map of England which was a great improvement upon that of Smith. At the same time Leopold von Buch prepared a similar map of a large part of Germany. A geological survey of France was ordered by the French government, by which a complete geological map of France was constructed in 1841. M. Bronard, professor in the school of mines, was appointed to take charge of the work, and he was associated with Elie de Beaumont and others. The attention of these geologists was first given to an examination of the coal formation of England, which had been most carefully studied and described by Conybeare and Phillips in their treatise on "The Geology of England and Wales" (1821). The second geological map of France, which many also were familiar to, was published in 1830. Both countries consequently became important points of reference for the groups of France. The tertiary formation of Paris, the upper member of the tertiary, served as the starting point, and proceeding from this they examined the lower strata as they appeared, emerging from beneath it, and identifying them with the corresponding strata of other countries.

as they could, with the corresponding groups of other countries. Such is the method ever since pursued, by which our knowledge of the strata which make up the outer crust of the earth has been systematically extended. The importance of the organic remains found in the rocks has been more and more appreciated, and the shells constituting the chief portion of these have been most thoroughly studied; for while the different formations or groups of strata may contain numerous similar beds of limestone, sandstone, slates, and shales, not to be distinguished by their mineral characters, and which frequently cannot be traced to their meeting with other known formations by which their place or relative positions may be determined, the fossils show no such indiscriminate distribution. Each period was characterized by its peculiar group of animated beings, and if their arrangement is understood it follows that the position of any stratum in which the fossils are recognized must also be determined. A single species may in some cases be peculiar to one member of a geological formation, and serve wherever the fossil is found to identify the rock; but usually in different countries their identification by fossils is dependent upon characteristic genera and the order of succession of their principal groups. This branch of the subject will be more particularly treated in the article PALEONTOLOGY.—In the latter part of the last and early part of the present century papers upon geological subjects occasionally appeared in the transactions of the American philosophical society of Philadelphia, the transactions of the American academy, and in other scientific journals. The character of these papers is almost exclusively descriptive. There is, however, a theory of the earth proposed by Franklin in the "Philosophical Transactions" of 1793; and in vol. vi. appeared the memorable essay of William Maclure, read Jan. 20, 1809, entitled "Observations on the Geology of the United States, explanatory of a Geological Map." The author of this paper had undertaken a more arduous and gigantic work even than that which was occupying William Smith of England; it was no less than a geological survey of the United States alone and at his sole expense—a work which entitled him to the appellation he has received of the father of American geology. In this pursuit he crossed the Alleghanies fifty times, visited almost every state and territory in the Union, and for years continued his labors mostly among those who could have no appreciation of his objects. He had visited nearly all the mining districts of Europe, and thus was well qualified, for one of that period, to recognize the corresponding formations of the two continents. He traced out the great groups of strata then designated as the transition, secondary, and alluvial, in their range from the St. Lawrence to the gulf of Mexico. The tertiary, however, he did not recognize, owing to the absence of the chalk formation, the upper member of the

secondary, which in Europe, being largely developed and most conspicuous, marks the strata of more recent origin lying above it as tertiary. He continued his explorations after this report, and in May, 1817, presented another to the philosophical society, accompanied by a colored map and sections. His observations were also extended in 1816 and 1817 to the Antilles, and a paper upon the geology of these islands was published in the first volume of the "Journal of the Academy of Natural Sciences." Prof. Silliman of New Haven, educated to the profession of the law, was induced by President Dwight of Yale college to qualify himself for the departments of natural science, particularly chemistry; and with this view he spent some time previous to 1806 in England and Scotland. In Edinburgh he became familiar with the discussions of the Wernerians and Huttonians in that transition period, as he styles it, between the epoch of geological hypothesis and dreams and the era of strict philosophical induction in which the geologists of the present day are trained. The interest excited by this controversy could not fail to direct his tastes toward the new science, and he returned to become its zealous promoter, for half a century or more aiding to elucidate the geology of his country, inspiring the enthusiasm of others, and furnishing in the "American Journal of Science" an organ for the diffusion of scientific knowledge. At that period (1804-'5), he says, geology was less known in the United States than mineralogy. Most of the rocks were without a name, except so far as they were quarried for economical purposes, and classification of the strata was quite unknown. Dr. Archibald Bruce of New York commenced in 1810 the publication of a journal devoted principally to mineralogy and geology, the earliest purely scientific journal supported by original American communications. It was well received at home and abroad, but appeared only at wide intervals, and ended with the fourth number. The mineralogical collections at the principal colleges, and others belonging to scientific men mostly in New York, promoted inquiry and observation concerning the geological relations of the minerals and their distribution. The admirable treatise on mineralogy by Prof. Parker Cleaveland, published in 1816, fostered while it gratified this spirit of inquiry. In 1818 the brothers Prof. J. F. Dana and Dr. Samuel L. Dana published a detailed report on the mineralogy and geology of the vicinity of Boston. In the same year was first published the "American Journal of Science," which has continued ever since to be the chief periodical American recorder of the progress of the sciences. The next year the American geological society held its first meeting at New Haven, where it continued to meet annually for several years. The importance of geological explorations, with the view of thereby ascertaining the agricultural and mineral capacities of large districts, was be-

ginning to be appreciated by communities and public bodies. In 1820 a geological survey of the county of Albany, N. Y., was made under the direction of the agricultural society of the county by Prof. Amos Eaton and Dr. T. R. Beck. Two years afterward Rensselaer and Saratoga counties were also thus explored. Prof. Eaton was also engaged by Gen. Stephen Van Rensselaer to make at his expense a geological survey of the country adjacent to the Erie canal. The result of this was published in 1824 in a report of 160 pp. 8vo, with a profile section of the rock formations from the Atlantic ocean through Massachusetts and New York to Lake Erie, the Rev. Edward Hitchcock furnishing many of the details through Massachusetts. The first geological survey made by state authority was that of North Carolina in 1824 and 1825, by Denison Olmsted. Since that time there have been various surveys by the different states or by the federal government, of which we shall notice the most important historically. Beginning at the northeast, early surveys were made of Maine, New Hampshire, and Rhode Island, by Dr. C. T. Jackson, in 1836-'41; of Massachusetts, by Edward Hitchcock, in 1830-'40; of Connecticut, by J. G. Percival and C. U. Shepard, in 1836, and of Vermont in 1845-'6, a work which was continued by Edward Hitchcock and his son, C. H. Hitchcock, in 1858-'60, the latter of whom is now (1874) engaged in a resurvey of New Hampshire. In 1836 was commenced the survey by H. D. Rogers and his assistants of the state of Pennsylvania, which was not completed till 1855. The survey of New York in 1836-'42, by Vanuxem, Emmons, Mather, and Hall, may be said to have opened a new era in American geology by giving a complete and systematic classification of the palæozoic rocks within its borders, which has served as a basis for all subsequent work to the east of the Rocky mountains. The description of the organic remains of the state by Prof. James Hall is still incomplete, but five large quarto volumes have been published. The surveys of Michigan in 1837-'46 by Houghton, and of the Lake Superior region in 1847-'9 by Jackson, and subsequently by J. D. Whitney and J. W. Foster, served to extend our knowledge of the palæozoic rocks to the westward. From that time to the present systematic surveys of the various states of the great Mississippi valley have been or still are in progress, and have already given us a pretty accurate knowledge of the geology of the whole of this vast region. The history of this work is too long for the present occasion, and it may seem invidious to mention names among workers in this great field; but a prominent place should be given, in addition to those just mentioned, to D. D. Owen, B. F. Shumard, Swallow, J. T. Hodge, Worthen, Newberry, Safford, E. W. Hilgard, Cox, and Tuomey. Nor should the important labors of Oscar Lieber in South Carolina and of Emmons in North Carolina be forgotten,

nor the elaborate survey of Virginia by William B. Rogers, of which only partial reports have been published. The geology of the western portion of our continent presents characters widely different from that already noticed and is now attracting great attention. Most important information was gathered by the labors of W. P. Blake and J. S. Newberry in the course of the great railroad surveys undertaken by the national government; and the geological work has been continued in the important survey of the 40th parallel under Clarence King, and that of the Rocky mountain region by J. V. Hayden. These labors are still in progress, as is also a geological survey of California under J. D. Whitney, and the great geological features of this region are being rapidly made known. Much progress has also been made in the study of the geology of British North America. A geological survey of Canada, embracing the present provinces of Ontario and Quebec, was begun in 1842 under Sir W. E. Logan, with whom were associated for many years Mr. Alexander Murray and Dr. I. Sterry Hunt. In 1870 Mr. A. R. C. Selwyn succeeded Logan in the present Dominion of Canada, including the British territory west to the Pacific, the field of the survey being thus greatly extended. The provinces of Nova Scotia and New Brunswick were early examined by Gesner, since which time Mather, Bailey, Hartt, Hind, Hunt, and Dawson have done much to develop their geology. The last named has especially studied the carboniferous rocks of that region. A survey of Newfoundland is in progress under Alexander Hector, Hind, and others, have done much to elucidate the structure of the geology north of Canada, until lately known as Hudson Bay territory.—With this knowledge of the progress of geological research in America, we may now proceed to state the general principles of geology, and to illustrate them by special reference to American geology. The great principles introduced by Werner remain the same, but many alterations in his numerous subdivisions and reclassifications have since been adopted, some of which are now in vogue. Besides the great divisions of crystalline and uncrystalline, or stratified and unstratified rocks, we have hence not to their primary position, but to their geognostical position. Crystalline rocks include all those which are crystalline, and are arranged in beds or masses, and are either igneous or not; and the uncrystalline rocks include granites, traps, basalt, and other rocks which occur in masses which are not stratified, and appear to have been introduced into their present position while the crystalline rocks were less softened or molten. These rocks are often spoken of as intrusive rocks. They are crystalline, and in certain cases

distinguished from those crystalline stratified rocks in which the bedding is ill defined, either from having been obscure from the first or else obliterated by subsequent crystallization. There are strong reasons for believing that the stratified crystalline rocks, by a process of softening and subsequent displacement or eruption, gave rise to the unstratified rocks with which they are often mineralogically identical; and hence the names of indigenous and exotic crystallines have been proposed by Dr. Hunt to designate respectively the stratified and the eruptive rocks. A third class of crystalline rocks is also to be distinguished, viz.: those which occur as veinstones in the fissures of other rocks, and have probably been deposited from watery solutions. Such are the quartz and spars which form the gangue of many metallic ores, and a large part of the so-called granite veins. The rocks of this third class, from their mode of formation, are designated by Dr. Hunt as endogenous crystallines. It is in some cases impossible to determine from its mineralogical characters to which of these three classes a given crystalline rock belongs. The unstratified crystalline or eruptive rocks include the modern volcanic lavas, which are evidently the products of igneous fusion, and the whole class is therefore sometimes designated as igneous rocks. It is supposed however that many of these rocks, as for example the exotic granites, have never been in a state of igneous fusion, but have assumed a plastic condition by the intervention of water under great pressure and at a temperature far below that of fused lavas. They have hence been called by some geologists plutonic and by others hypogene rocks, the latter name signifying rocks generated beneath, in allusion to their obvious subterranean source. The distinctly stratified and sedimentary character of the great formations of crystalline rocks, and the obvious analogies which they present in this respect to the uncrystalline formations, early attracted the attention of geologists. In both occur intercalated layers of limestones, argillites, and conglomerates; and the question naturally arose as to the origin of the gneisses, mica schists, diorites, serpentines, chlorite schists, and talc schists, which are the characteristic rocks of these crystalline stratified formations. That the elements of these had in some way been deposited from water, like the beds of sand, mud, and carbonate of lime of uncrystalline strata, seemed obvious; and hence the conclusion that they were once, like the latter, uncrystalline strata, which had subsequently changed their form. In accordance with this notion, they were designated metamorphic strata, and this term is by many geologists used as synonymous with stratified crystalline rocks. It was noticed that in some instances uncrystalline sediments had assumed a crystalline character in the immediate vicinity of certain erupted rocks; the effect of heat, or more probably of the heated solutions impregnating the last, having generated

in the midst of the contiguous sediments crystalline mineral species. It was then possible that a formation uncrystalline in one part of its distribution should elsewhere become crystalline, or in other words metamorphic; and it was conjectured that great areas of such rocks might be the stratigraphical equivalents of formations which are elsewhere uncrystalline sediments. In the Alps, for example, it was supposed that the gneisses and other crystalline schists were of mesozoic and even of cenozoic age, and similar rocks in other regions were declared to be palæozoic; till at length it seemed, such was the extension of the doctrine of rock metamorphism, that the sediments of any age might assume the characters of the primitive crystalline schists. In fact, the crystalline schists of the Alps, the British islands, and the Appalachians have all in turn been claimed as altered strata of palæozoic or more recent times. But these views have been controverted, and it has been shown that the crystalline strata which are now found in the Alps, superposed upon the uncrystalline fossiliferous sediments, are really ancient strata which were crystalline before the deposition of the latter, and in their normal position underlie them, but by great foldings and inversions have been brought to overlie them. In some instances in this region beds of apparently crystalline rocks are met with in which occur fossils like those of the uncrystalline sediments. These were regarded as further evidences of the metamorphic process which had proceeded so far as to develop a crystalline structure in the newer beds, without however obliterating their organic remains. But it has been shown that these pseudo-crystalline rocks are really sediments of the newer periods, made up of the ruins of the older and truly crystalline rocks. In many other cases, as in Wales and in eastern North America, it is found that the broken-up materials of the crystalline schists enter into the composition of the oldest palæozoic schists, which are themselves uncrystalline. While, therefore, it is clear that the crystalline schists were deposited from water, and, as will subsequently be seen, under conditions which, although chemically somewhat different from those of later times, did not prevent the development of organic life, it is now affirmed by one school of geologists that the great bodies of crystalline schists do not result from the alteration of any known series of uncrystalline strata; so that the division between the two established by Werner may still be retained as a fundamental one. This view is now sustained by Favre of Geneva, Sterry Hunt, Gumbel, Credner, and others; but the opposite view, which maintains a wide-spread metamorphism of palæozoic and more recent rocks, has been taught by very eminent names, and is still maintained in the principal geological text books and treatises. The partisans of the latter view, while asserting the comparatively recent origin of many crystalline schists, have always

admitted the existence of an underlying or basal system of stratified crystalline rocks, which were supposed to be anterior in their formation to the appearance of life upon the earth, and from the apparent absence of fossils were called azoic rocks (signifying without life). In accordance with this nomenclature, the formations containing the fossil remains of plants and animals have been divided into palæozoic, mesozoic, and cenozoic rocks (signifying ancient, middle, and recent life); while subsequent discoveries, indicating that life had already made its appearance in the so-called azoic period, have led to the substitution of the name eozoic (signifying the dawn of life). These four great divisions are made the basis of the

accompanying tabular view of geological formations. The subordinate divisions of Cambrian, Silurian, Devonian, &c., are of local origin, which, as will be seen, is also true of names of most of the formations into which these in their turn are divided. In regard to the palæozoic rocks, which have been minutely studied in Great Britain and in the names of the subdivisions recognized in these countries are given side by side. For details of the mesozoic and cenozoic rocks which have been made the subject of not careful analysis and subdivision in Europe the reader is referred elsewhere. A complete list of them is given on page 109 of Lyell's "Elements of Geology" (1871).

		BRITISH SUBDIVISIONS.	AMERICAN SUBDIVISIONS, WITH REMARKS.
CENOZOIC, OR TERTIARY.		Recent .....	Alluvial deposits, peat bogs, &c.
		Post-pliocene.....	Unstratified glacial drift, modified drift, &c.
MESOZOIC OR SECONDARY.		Pliocene.....	Widely distributed along the eastern and southern coasts from Massachusetts to Texas, and from Nebraska across the continent to the Pacific.
		Miocene .....	
		Eocene.....	
	CRETACEOUS.	Upper cretaceous .....	Occurs in New Jersey, Georgia, Mississippi, Arkansas, &c., and from the upper Missouri in many localities westward to the Pacific.
		Lower cretaceous or Neocomian.....	
	JURASSIC.	Upper, middle, and lower oolite .....	Widely developed in the western states in various localities from Idaho to the Pacific.
		Lias .....	
	TRIASSIC.	Upper, middle, and lower trias .....	Red sandstones of the Connecticut valley, New Jersey, Pennsylvania, and fields of Richmond, Va., and Chatham, N. C.
	PERMIAN.	Magnesian limestone.....	Permian ..... Known in Illinois, Iowa, and Kansas.
PALÆOZOIC OR PRIMARY FOSSILIFEROUS.	CARBONIFEROUS.	Coal measures.....	Coal measures ..... } To this horizon belong the coal formations of New Brunswick, Rhode Island, Michigan, and the great Appalachian coal field.
		Millstone grit.....	
		Carboniferous limestone.....	
	DEVONIAN.	Upper, middle, and lower Devonian.....	Catskill. Portage and Chemung.... } The Erie division of the New York series. Dawson uses Erian as synonymous with Devonian.
	SILURIAN (Sedgwick).	Upper and lower Ludlow. }	Oriskany ..... } The upper Silurian of Murchison, the third of Barrande. The stratigraphical break at the top of Silurian makes two great divisions of the Silurian.
	CAMBRIAN (Sedgwick).	Caradoc or Bala.....	Hudson River..... } The lower Silurian of Murchison, or the fauna of Barrande.
		Llandello .....	
	Middle.	Tremadoc.....	Chazy ..... } These include the prime Cambrian of Murchison, the first of Rogers, the Tremadoc group of Logan, and the first fauna or primordial zone.
		Lingula flags.....	
	Lower.	Menevian.....	
		Harlech.....	
EZOIC.		Laubmois.....	
		Primitive crystalline schists (Urchiefer) .....	Norian or Labrador..... } Above the Laurentian, and probably in the here given.
		Primitive gneiss (Urgeineis). .....	Montalban or White Mt.... } Dana uses the name Archæan as with Eozoic.

It should, however, be borne in mind that all such divisions of the rocks are arbitrary and artificial. From the time when they have been deposited,

of sea and land, it follows that there are breaks in the succession of the rocks, which are often marked by a want of conformity in the arrangement of the successive formations. The sea retires from an uplifted continent, the strata become more or less disturbed, and perhaps in the course of ages partially broken down and swept away. When a new movement of the earth's crust brings this region once more beneath the sea, a new series of beds resting horizontally upon the older formation is deposited, and we have evidence, both from the relations of the strata and from the changes in the organic remains, of a break in the succession. Yet it is clear that elsewhere in the region occupied by the sea during this interval would be deposited sediments which fill up the interval. The process of deposition of sediments in the sea has never been interrupted, though the area of deposition has changed, and all breaks in the succession are local and accidental interruptions. Our divisions into systems and groups have been based in great part upon these interruptions, corresponding to omitted leaves in the succession, which the progress of investigation is now gradually supplying, so that the record when completed will show no breaks and no interruption either in the deposition of strata or in the succession of the forms of life. The disturbances or cataclysms which in the theories of the older school of geologists were looked upon as universal are really local, and are dependent upon the disturbances due to slow movements and the transfer of the process of sedimentation to other regions. But it is precisely where these breaks have been noticed that geologists have established horizons or lines of demarcation upon which the systems of classification have been built. From time to time we find out the formations which in other regions correspond to these interruptions, and serve to show the transition from one of the periods to another. These limits between hitherto separated formations are designated beds of passage. It is proposed to give a brief sketch of the successive geological groups enumerated in the preceding table, commencing with the lowest or eozoic period, and to notice the principal facts in their history, more especially as seen in North America.—The rocks which we have called eozoic include the crystalline strata, which are regarded in the present state of our knowledge as forming four great groups marked by lithological differences. At the base we have placed the Laurentian, which consists in great part of granitoid gneiss, in which, but for the interposed strata of quartzite, crystalline limestone, &c., there would in many parts be found small evidence of its stratified origin. This ancient group is what is called in Scandinavia the primitive gneiss, and corresponds to the fundamental granite which is often spoken of as underlying all other rocks. It is the oldest series of rocks known, and in North America forms a large part of the Lau-

rentides, the Adirondacks, the Highlands of the Hudson, and their continuation southward. The thickness of this great series is unknown, but Sir William Logan has estimated that at least 20,000 ft. of strata belonging to it are exposed on the Ottawa river. It there includes three great limestone formations, which are associated with iron ore, plumbago, and phosphate of lime, and contain the remains of a foraminiferous organism to which Dawson has given the name of *eoosoon Canadense*. To the Laurentian succeeds what has been named the Huronian, a group of crystalline rocks much more schistose than the Laurentian, and consisting of imperfect gneisses, with micaceous, chloritic, and talcose schists, and beds of hornblende and serpentine rocks, associated with argillites and magnesian limestones. This series is widely spread along both the N. and S. shores of Lake Superior, and the N. shore of Lake Huron, and constitutes the Green mountain range of eastern Canada and New England, stretching thence northeastward into Newfoundland and southwestward along the Appalachians. Rocks apparently belonging to this series fringe portions of the E. coast of New England, and are seen in a wider development in the coast range of southern New Brunswick. In some parts of the Lake Superior region the Huronian rocks are found to rest unconformably upon the Laurentian, and to be made up in part of its ruins, thus indicating a break between the two series. The third great group noticed in our table is that of the White mountains, or, as it may be called, the Montalban series. It consists in great part of gneisses, which, however, are lithologically dissimilar from those of the Laurentian, and are associated with large bodies of highly micaceous schists, abounding in kyanite, staurolite, andalusite, and garnet. This series of rocks is traced from the White mountains northeastward across the state of Maine and southwestward throughout the Appalachians. The facts, so far as known, seem to show that it is newer than the Huronian, resting unconformably upon it, and in some places probably upon the Laurentian in the absence of the former. The fourth group is what has been called the Norian or Labradorian, which consists in great part of granitoid or gneissoid varieties of the rock called norite, consisting chiefly of Labrador feldspar. With this are associated gneisses, quartzites, and crystalline limestones not unlike those of the Laurentian. This series in various parts of Canada and in northern New York appears to rest unconformably on the Laurentian, and was hence called by Sir William Logan the upper Laurentian; but according to recent observations by Hitchcock, it occurs in New Hampshire, apparently overlying the White mountain series. Dr. Sterry Hunt, who is the author of this attempt to group and classify the eozoic rocks, remarks: "The distribution of the crystalline rocks of the Norian, Huronian, and

Montalban series suggests that they are remaining fragments of great formations once widely spread over an ancient floor of granitic (Laurentian) gneiss; but that these four series mentioned include the whole of the stratified crystalline rocks of North America is by no means certain. How many more formations may have been laid down over this region and subsequently swept away, leaving only isolated fragments, we may never know; but it is probable that a careful study may establish the existence of many besides the four series above enumerated." Notwithstanding the distinction which has been drawn between crystalline and uncrystalline rocks, there is probably to be found somewhere a series of beds marking the passage from these crystalline schists to the uncrystalline sediments of the palæozoic, although, so far as yet studied, the oldest known strata hitherto referred to the latter are completely uncrystalline, and rest unconformably upon crystalline eozoic rocks. There appears to be a close similarity between the latter in widely separated countries, the great series already indicated being recognized with their typical characters in remote parts of the globe.—The palæozoic rocks have been divided into five great groups, sometimes called systems; but these divisions, as already remarked, are local, and the breaks in stratification and in the succession of organic remains are in some parts filled by beds of passage. As will be seen in the table, there is some difference in the nomenclature of the lower palæozoic rocks, a portion of the Cambrian of Sedgwick being included by Murchison in the Silurian. In the present account we shall use these terms in the sense in which they were applied by the former. The lower portions of the palæozoic show no evidence of terrestrial forms of life, their vegetable remains consisting of algæ, and their animals of mollusks, corals, and crustaceans. At the summit of the Silurian, however, fishes and amphibians appear, while an abundant land vegetation of acrogens and gymnosperms begins to make its appearance. The palæozoic rocks are of especial interest to the student of American geology, as they form the surface of the greater portion of the United States east of the Rocky mountains. The succession of the members of the palæozoic series in this country was first clearly defined by the geological survey of New York, which in its reports in 1842 included under the name of the New York system the whole of the known palæozoic rocks to the base of the coal formation. The subdivisions then established have since been generally adopted in the United States, and their relations to those recognized in Great Britain will be seen in the table. The names Cambrian, Silurian, and Devonian found their way into American nomenclature some years later. For an account of the progress of discovery in these rocks, the reader is referred to the third part of a paper on "The History of Cambrian and Silurian," by Dr. Hunt, in the "Canadian Nat-

uralist" for July, 1872. The lower and middle Cambrian is represented in the New York series by the Potsdam sandstone, and the calciferous sand rock, having a combined thickness of less than 1,000 ft. To the eastward along the confines of New England, and thence westward along the base of the Green mountain range, however, a series of 10,000 ft. or more of sandstones, argillites, and limestones (including the Levis formation), is regarded as the representative of the lower and middle Cambrian, and has received the names of the Taconic system and the Quebec group. Still further east, along the E. coast, in Massachusetts, New Brunswick, and Newfoundland, are found strata of lower Cambrian age, referred to the Menavian of Great Britain. Between the middle and the upper Cambrian in New York is a break marked by a change in the fauna, and in some localities by a want of conformity between the strata. The Chazy limestone, which in some places is wanting, shows the passage between the two. The upper Cambrian is represented by the limestones of the Trenton group, followed by the Utica slates and the shales and sandstones of the Hudson river group; the last three divisions being known in Ohio as the Cincinnati group. Succeeding this occurs the Oneida conglomerate, followed by the Medina sandstone rocks, which are in part derived from the ruins of the underlying rocks which mark a period of disturbance in the succession. They are succeeded by the Clinton, Niagara, and Onondaga. The latter, sometimes known as the Onondaga limestone, is characterized by beds of gypsum, and is succeeded by the lime beds, which, as well as the rest of this division, from the westward, consist chiefly of limestone. This upper Silurian represents the division separated from the open ocean by its gradual evaporation. At the close of this period, the strata associated with it are most destitute of organic remains. A considerable thickness of these strata is found in central New York, but they are not continuous and disappear before reaching the coast. To this division succeed the Onondaga limestones, characterized by their fossiliferous nature and marking by their position the geological condition which a deposit of this kind would be alike over all the coast. The Onondaga, toward, resting upon the Cambrian and the Silurian in eastern Canada, where it is overlain by the Onondaga limestones, represents the boundary between the subsequent Devonian series, is marked by the Onondaga sandstones, followed by the Onondaga stone and the Onondaga. These rocks make up the upper Cambrian, succeeded by a series of

constituting the Erie division of the New York series, the equivalent of the English Devonian or old red sandstone, and characterized by an abundant terrestrial fauna, the precursor of that of the carboniferous series, into which it passes by such transitions that it is a matter of discussion where to draw the line. The carboniferous series is so named because it is the earliest and most important coal-bearing series of strata, and includes great beds of fossil fuel, interstratified with sandstones and shales. At the base of the carboniferous in Michigan, Pennsylvania, and western Virginia, and also in Nova Scotia and New Brunswick, deposits of gypsum and salt are met with. In the western part of its distribution, toward the Mississippi, the carboniferous formation includes great thicknesses of marine limestone, which are wanting in the east. Overlying the carboniferous in Kansas and Iowa are beds which are the equivalent of the magnesian limestones of the north of England, and of the rocks called Permian in Russia. They are regarded as the summit of the palæozoic series.—The palæozoic rocks correspond to the transition rocks of Werner, to the lower part of which the name of the graywacke series was very generally given until the labors of Sedgwick and Murchison classified them and established the great divisions of Cambrian, Silurian, and Devonian. The thickness of these groups varies greatly in different parts of their distribution. Thus, while the entire palæozoic series in Pennsylvania is estimated at 40,000 ft., it is reduced to 4,000 in the valley of the Mississippi. This is due to the fact that the great sandstones, apparently derived from the erosion of rocks to the eastward, thin out in the opposite direction. In a similar manner the Cambrian and Silurian rocks, which attain in Great Britain a thickness of 30,000 ft., are represented by less than 2,000 ft. in Scandinavia.—Under the name of mesozoic or secondary rocks are included the triassic, Jurassic, and cretaceous series. The former has received its name from the threefold division of it in Europe into sandstones, overlaid by fossiliferous limestones, which are succeeded by sandstones and shales. At the base of the trias in the Tyrol, at St. Cassian and Haltstadt, occurs a series of fossiliferous beds in which the characteristic animal remains of the trias are found mingled with those of the palæozoic, thus showing a passage between the palæozoic and the mesozoic rocks. The trias, both in England and on the continent of Europe, is characterized by beds of rock salt and gypsum, like the Silurian and the lower carboniferous in North America. The sandstones of the trias in England are often red, and constitute what is there named the new red sandstone. The same name is applied to sandstones of similar age which are found in Prince Edward island and Nova Scotia, in the valley of the Connecticut, and in New Jersey, Pennsylvania, Virginia, and North Carolina. To this series belong the coal fields of Rich-

mond, Va., and Chatham, N. C. It is not improbable that these beds may include strata belonging to the subsequent or Jurassic period, so named because it is greatly developed in the Jura mountains. This includes both the lias and the oolite of England, which two on the continent are connected by beds of passage known as the Koessen or Rhætic strata. The oolite of England consists of highly fossiliferous strata, chiefly marine, but in part fresh-water deposits, and through the Neocomian (Neufchâtel) beds passes into the cretaceous or chalk formation, the upper part of which is characterized in northern Europe by that pure uncrystalline limestone known as the chalk, a deep-sea deposit many hundred feet in thickness, made up almost entirely of the remains of minute animal organisms.—The rocks of the cenozoic or tertiary period are closely connected with the present time, and even in their lower portions contain some species of fossil shells identical with those now living. Lyell has conveniently divided the tertiary, in ascending order, into eocene, miocene, and pliocene; to these are added a postpliocene division which includes the period of glacial drift. (See DILUVIUM.) The tertiary rocks attained a great thickness in some parts of their distribution. Thus in the Alps the miocene sandstones and conglomerates, known as the molasse, have in parts a thickness of more than 6,000 ft., while the nummulitic limestone, a subdivision belonging to the base of the tertiary, attains in the Mediterranean basin a thickness of more than 2,000 ft.—We have already spoken of the trias of the eastern part of North America. The cretaceous is also represented in New Jersey and along the southern border of the palæozoic from Georgia to Tennessee. Triassic, Jurassic, and cretaceous rocks are also widely spread between the Mississippi and the Rocky mountains, from Texas to Dakota, and westward over large areas to the Pacific coast. Deposits like the English chalk are unknown in this formation in North America. Tertiary rocks of various ages skirt the Atlantic coast from the Rio Grande to New Jersey, and are even met with off the coast of Massachusetts. They stretch from the gulf of Mexico to Kentucky, and like the mesozoic rocks occupy large areas to the westward, where on the Pacific coast they attain great thickness.—The succession of organic life in these various groups constitutes a study by itself, which will be considered under the head of PALÆONTOLOGY. The palæozoic age is preëminently the period of mollusks, corals, and crustaceans, the most important class of which last in the early times were the trilobites, which appear in their greatest development in the Cambrian and Silurian, and die out in the carboniferous. Fishes, the earliest representatives of vertebrate life, make their appearance near the summit of the Silurian, and abound in the upper palæozoic; reptiles first appear in the carboniferous, and reach their greatest development in the mesozoic, in which rep-

tilian forms of immense dimensions, and having curious resemblances to birds, are met with; while the birds themselves, which then first appeared, had remarkable reptilian affinities. The earliest evidences of mammals appear in the trias; throughout the mesozoic they were insignificant in size, and chiefly marsupial. In the eocene and miocene divisions of the tertiary we find the greatest development of mammalian forms. The deposits of these strata to the west of the Mississippi have within the last few years afforded a great number of remarkable species of mammals, which have been described by Leidy, Marsh, and Cope. The flora of the tertiary period is not less remarkable than its fauna. The geographical and climatic conditions of the northern hemisphere were then widely different from those of the present day. Not only over Europe, but in North America, and northward as far as Greenland and Spitzbergen, a mild and equable climate prevailed, and the abundant plant remains preserved in the tertiary beds of those arctic regions show a luxuriant vegetation like that of the warmer parts of the temperate zone of to-day. This condition of things had been of long continuance; for in western America great beds of coal or lignite are found both in the cretaceous and the eocene strata. It was continued far into the pliocene; but as this went on, a cold climate like that which now characterizes the northern hemisphere prevailed, and gave rise to the glacial phenomena which have been described under the head of *DILUVIUM*. This change of climate is one of the most perplexing problems of geology. That a different distribution of land and water and of the oceanic currents may have contributed in some degree to this former climatic condition of the arctic regions is probable. Astronomical conditions connected with changes in the eccentricity of the earth's orbit have also been suggested as a cause; and finally it has been supposed that a somewhat different chemical composition of the earth's atmosphere prevailing up to that time may have coöperated with geographical conditions to maintain the peculiarly mild climate which, so far as we can judge, prevailed throughout the arctic regions in paleozoic times, and perhaps without interruption nearly to the close of the tertiary.—The distribution of metallic ores and other economic materials in the various geological series is a point of much interest, and demands a brief notice in this place, although the subject is discussed more in detail under *MIXERAL VEINS*, and in the articles on the different metals. Metallic ores are met with both in beds interstratified with the rocky layers and in veins cutting these. The eozoic rocks are remarkable for their great development of crystalline iron ores, of which those of Laurentian on Lake Champlain and of Huronian on Lake Superior are examples, as are also those of Missourian deposits occur in the eozoic

rocks of Scandinavia and Russia. It is in these rocks also that titanite and chromic iron and emery occur; and to them belong graphite and beds of iron pyrites and copper pyrites often associated with gold and with silver. Oxide of tin also appears to be characteristic of these crystalline rocks. These various ores are found not only in contemporaneous layers but also in veins and beds cutting the crystalline strata. But the metallic ores are not confined to these more ancient rocks, for beds of oxide and carbonate of iron are met with at various horizons from the Cambrian up to recent times, while under the heads of *COPPER* and *GOLD* the distribution of those metals and their ores is described. Besides these contemporaneous deposits, veins or lodes carrying the ores of various metals are found cutting rocks of all ages, and are probably even now in process of formation.—The question of eruptive or exotic rocks has already been briefly alluded to, but from its intimate connection with volcanic phenomena, from which it cannot well be separated, it is proposed to consider the whole subject in the article *VECANO*, in which connection the various theories with regard to the nature of the earth's interior, the sources of subterranean heat and of ancient and modern eruptive rocks, as well as of the gaseous products of volcanic eruptions, will be discussed. (See also *GEOMORPHOLOGY*.) Under the head of *MOUNTAINS* will be considered some of the most important questions of geological dynamics, namely, those relating to the elevation of continents, the phenomena of denudation, and the origin of mountains. The chemical history of the globe, or what may be called chemical geology, will be discussed under the titles *ROCKS* and *WATER*.

**GEOMETRY** (Gr. *γεωμετρία*, fr. *γῆ*, earth, and *μετρέω*, to measure), the science of the relations in space. As its name indicates, it originally denoted the measurement of land, and was equivalent to what is known at present times as surveying. As at present surveying is but a subordinate branch of the science, and although geometry has its ancient name, it has by the progress of successive generations grown into a comprehensive system, for which many of the most important questions have been defined as "the science which treats of forms in space;" and its scope is sufficiently extended to include not only "form," the definition of which is any other. It regards matter in so far as they occupy space. It considers physical qualities, their combinations, &c., geometry has nothing to do with that a billiard ball and a perfect sphere, then the only difference between them is the difference in their nature. Neither has geometry any connection with the nature of space abstractly considered, nor does it assume the notion of infinity. It is a science of men in practical life, and

the discussion of its nature. It assumes that space is infinite in extent; that is, it assumes as undeniable, and therefore as requiring no proof, that we can neither in fact nor in thought set any boundary to space and rightfully say there is no space beyond. It assumes that space is infinitely divisible; that is, that no portion of space is so small that we cannot conceive it as being divided. Finally, it assumes that space is continuous; that is, that which separates any two definite portions of space is itself space. Any definite portion of space, whether occupied by a body or not, is in geometry called a solid or volume, and the property of a body by virtue of which it occupies space is called extension. Extension is said to have three dimensions, length, breadth, and thickness. The limits of a solid are called surfaces, and are said to have length and breadth without thickness. The limits of a surface are called lines, and are said to have length without breadth or thickness. The limits of a line are called points, and are said to have neither length, breadth, nor thickness, but position only. A point may be considered independently of any line, a line independently of any surface, and a surface independently of any solid. The definitions of these fundamental notions of geometry have always been matters of controversy among geometers and philosophers, but practically all men are agreed as to its nature. The idea of space involves three notions which are indissolubly connected, viz.: position, direction, and magnitude. Starting from any given point, we can suppose lines to be drawn in an infinity of different directions. The difference in the direction of any two of these lines is called an angle. A line whose direction is everywhere the same is called a straight or right line; a line which changes its direction at every point is called a curved line. When the word line is used alone, and there is nothing to indicate the contrary, a straight line is always meant, and a curved line is usually called simply a curve. In treating of forms in space, straight lines, angles, and curves, and their mutual relations, are the principal things which the geometer has to consider. The object of geometry is the indirect measure of magnitude. To measure a magnitude is to find how many times it contains a known magnitude of like nature with itself, which is assumed as a unit. Thus, to measure a line is to find how many times it contains a line of known length, as an inch, a foot, a yard, a metre; to measure a surface is to find how many times it contains a known surface, as a square inch, a square foot, a square yard, a square metre, an acre, a square mile; to measure a solid is to find how many times it contains a known solid or volume, as a cubic inch, a cubic foot, a cubic yard, a cubic metre, a cubic mile. To measure a straight line, the most obvious method is to apply to it the assumed unit, for example, a foot, and count the number of times the line to be measured

contains it. This method of measurement is purely mechanical, and geometry has nothing to do with it; it is a question, not of geometry, but of physics and arithmetic. In many cases, as in measuring the height of a mountain, this method is impracticable; in many others, as the distance of the moon from the earth, it is impossible. And when we pass from the measurement of straight lines to the measurement of curves, surfaces, and solids, we find that in almost all cases the mechanical method is either impracticable or impossible. Thus the every-day problem, to find how many acres there are in a farm, would, in the absence of all geometrical knowledge, remain for ever insoluble. It is evidently necessary to find some method of measuring indirectly that which we cannot measure directly. Thus in the case of a farm we can measure by mechanical means the length and directions of its boundary lines, and then geometry teaches how, knowing these, we can find the number of acres it contains. Let us take as another example a problem of a higher kind. From the observation of certain physical facts men long ago concluded that the earth was a spherical body. A great number of interesting questions immediately presented themselves. What was its diameter? How many square miles did its surface contain? Were all its diameters equal? To answer these questions by direct measurement was impossible; all that could be done was to measure here and there a line upon its surface. Yet with the aid of a few direct measurements and of the principles of geometry all these questions have been answered. It is evident that the attainment of these results would be hopeless, and that geometry would be impossible, unless the different magnitudes of space and the elements of which each magnitude is composed were related to each other according to certain fixed and definite laws. The number of different forms in space is infinite, and unless their relations to each other were fixed and definite, and they were susceptible of classification and comparison, there could be no science of geometry. The same would be the case if the different magnitudes which are the elements of every form were not connected by definite relations. Geometry shows that they are so related, and explains the nature of those relations. — According to the different points of view from which it is regarded, geometry is variously divided. Its primary division is into elementary and higher geometry. Elementary geometry treats of angles, straight lines, planes bounded by straight lines, solids bounded by planes, circles, cylinders, cones, and spheres. The treatment of all curves except the circle, and of all surfaces and solids which involve the consideration of any curve other than the circle, belongs to higher geometry. The only instruments necessary for the construction of the figures employed in treating of elementary geometry are the rule and

compasses. If the solution of a problem requires in its graphic representation a line which cannot be drawn by means of these two instruments, it was not considered by the ancient Greek geometers a geometrical solution. Elementary geometry is sometimes subdivided into planimetry and stereometry, the former treating only of such lines and figures as lie in a plane, the latter of solids bounded by planes, and of the sphere, cone, and cylinder, which are usually designated as the three round bodies. That part of planimetry which treats of the measurement of triangles, and shows how, the magnitude of certain parts of a triangle being given, the magnitude of the other parts can be found, is called trigonometry, and, on account of the peculiarity of the methods which it employs, is usually treated as a separate branch of geometry. Geometry again is divided into synthetic and analytic, or ancient and modern, or special and general; divisions which all signify the same thing, and are based upon the difference between the methods which are employed in them respectively. Synthetic, ancient, or special geometry is founded upon the direct observation of the forms or figures themselves, and all its reasonings are conducted with direct reference to those figures. Thus, in treating the ellipse, the first thing to be done, according to this method, is to draw an ellipse upon a plane, or to draw a representation of a cone with a plane passing through it obliquely to its axis, or in any other convenient way to bring before the mind the actual figure; next, to draw such other lines as the course of the reasoning may require; and lastly, to demonstrate, in accordance with the rules of logic and previously established propositions, the different proportions of the figure. This method, when compared with the analytic, modern, or general method, of which we shall presently speak, possesses great advantages and disadvantages. Among the former we mention that it is evidently the natural method, that is, the method to which the human mind naturally would and must resort in its first attempts to investigate the relations of space. It keeps not only before the mind but before the eyes the actual thing whose nature we are investigating, and constantly calls upon the hands to do what the mind has conceived. As a mental discipline, geometry studied in this manner is not surpassed, perhaps not equalled, by any other science. Especially in the solution of problems reason, ingenuity, and imagination are all called into exercise. This method was the only one known to the ancient Greeks, and they regarded geometry as holding the highest rank among the sciences. Plato is said to have inscribed over his door, "Let no one enter here who is unacquainted with geometry." The analytic or modern method is, as to its form, characterized by the application of the processes of algebra and the calculus to the discussion of the relations of space. But its

true nature consists in its generality. The ancient geometry was essentially special. Thus the study of one curve was of little or no advantage in the study of another, except in so far as it had trained and strengthened the mental powers. The problem to draw a tangent to any point of a curve affords striking example of the difference between the two methods. When the ancient geometer had discovered a method of drawing a tangent to any point of the circle or the ellipse, this did not aid him in drawing a tangent to the curves called the conchoid and the cisoid. Whenever a new curve was discovered, the problem of drawing a tangent to it had to be solved anew, and independently of its solution in the case of any other curve. Modern geometry substitutes, in place of the consideration of the geometrical magnitudes themselves, the consideration of equations representing them according to a general system; and after the discovery of the differential calculus the problem above mentioned was solved with the greatest ease and simplicity by a formula applicable to every known curve and to every curve that may hereafter be discovered or invented. (See ANALYTICAL GEOMETRY.) Considered as a method of arriving at results, the modern is infinitely superior to the ancient; considered as a means of mental discipline, its superiority is disputable.—The history of geometry may be conveniently divided into five periods. The first extends from the origin of the science to about A. D. 550, followed by a period of about 1,000 years during which it made no advance, and in Europe was enshrouded in the darkness of the middle ages; the second began about 1550, with the revival of the ancient geometry; the third in the first half of the 17th century, with the invention by Descartes of analytical or modern geometry; the fourth in 1684, with the invention of the differential calculus; the fifth with the invention of descriptive geometry by Monge in 1795. The quaternions of Sir William Rowan Hamilton, the *Ausdehnungslehre* of Dr. Hermann Grassmann, and various other publications, indicate the dawn of a new period. Whether they are destined to remain merely monuments of the ingenuity and acuteness of their authors, or are to become mighty instruments in the investigation of old and the discovery of new truths, it is perhaps impossible to predict. According to a tradition handed down by the Greek historians of geometry, the science took its rise among the Egyptians. The inundations of the Nile annually obliterated their landmarks, and efforts to restore them gave rise to geometry. From them, about 600 B. C., Thales of Miletus, one of the "seven wise men" of Greece, is said to have derived a knowledge of the elements of geometry, and to have introduced it into Greece. Pythagoras is also said to have derived his first notions of geometry from the same source, and to him is ascribed the dis-

covery of the proposition, which still bears his name, that the square described on the hypotenuse of a right-angled triangle is equal to the sum of the squares described on the other two sides. His disciples are said to have demonstrated the incommensurability of the diagonal and side of a square, and to have investigated the five regular solids. They were also possibly acquainted with the transcendental definition of the circle, viz., that it is the figure which within a given perimeter contains the greatest area; and with the analogous proposition in regard to the sphere, that it is the body which within a given surface contains the greatest volume. About a century after Pythagoras, Plato and his disciples commenced a course of rapid and astonishing discoveries, through the study of the analytic method, conic sections, and geometric loci. The ancient analytic mode consisted in assuming the truth of the theorem to be proved, and then showing that this implied the truth only of those propositions which were already known to be true. In modern days the algebraic method, since it allows the introduction of unknown quantities as data for reasoning, has usurped the name of analytic. Conic sections embrace the study of the curves generated by intersecting a cone by a plane surface. Within 150 years after Plato's time this study had been pushed by Apollonius and others to a degree which has scarcely been surpassed by any subsequent geometer, and his works, embracing his predecessors' discoveries as well as his own, proved 19 centuries afterward the foundation of a new system of astronomy and mathematics. Geometrical loci are lines or surfaces defined by the fact that every point in the line or the surface fulfils one and the same condition of position. The investigation of such loci has been from Plato's day to the present one of the most fruitful of all sources of geometrical knowledge. Just before the time of Apollonius, Euclid introduced into geometry a device of reasoning which was exceedingly useful in cases where neither synthesis (i. e., direct proof) nor the analytic mode is readily applicable; it consists in assuming the contrary of your proposition to be true, and then showing that this implies the truth of what is known to be false. Contemporary with Apollonius was Archimedes (died in 212 B. C.), who introduced into geometry the fruitful idea of exhaustion. By calculating circumscribed and inscribed polygons about a curve, and increasing the number of sides until the difference between the external and internal polygons becomes exceedingly small, it is evident that the difference between the curve and either polygon will be less than that between the polygons themselves; and the process may be continued by increasing the number of sides, until the difference between the curve and the polygon is as small as we please. This method is generally regarded as the germ of the differential calculus. Hipparchus

in the 2d century before Christ, and Ptolemy in the 2d century after Christ, applied mathematics to astronomy; at the date of the latter writer the doctrine of both plane and spherical triangles had been well discussed by Theodosius and Menelaus. Vieta (1540-1603), to whom we principally owe the perfecting of algebra, enlarged Plato's analytic method by applying algebra to geometry. Kepler (1571-1630) introduced into geometry the idea of the infinitesimal, thus perfecting the Archimedean exhaustion; he also first made the important remark which leads to the solution of questions of maxima, that when a quantity is at its highest point its rise becomes zero. To Kepler we owe also one of the first examples of a problem of descriptive geometry, in the graphic solution of an eclipse of the sun. Soon after Kepler, Cavalieri published (1635) his *Geometria Indivisibilium*, a further step in the road from Archimedes's exhaustions to Newton's fluxions. Roberval gave a method of drawing tangents identical in its philosophy with fluxions. Fermat (who shares with Pascal the credit of inventing the calculus of probabilities) introduced the infinitesimal into algebraical calculation, and applied it with great success to geometrical questions. Pascal anticipated some of the latest inventions by his famous theorem concerning the relation of six points arbitrarily chosen in a conic section. But most wonderful of all the geometrical inventions of the 17th century was that of Descartes, published in 1637; it consisted simply in considering every line as the locus of a point whose position is determined by a relation between its distances from two fixed lines at right angles to each other. The relation between these distances, being expressed in algebraical language, constitutes the equation of the curve. By later geometers this method has been generalized so that the distances may be measured from any fixed point or line, and measured in a straight line or in a given curved line; or instead of some of the distances, directions or angles may be introduced. For a majority of the most important cases, however, Descartes's coördinates are still the best. Huygens, whose treatise on the pendulum is ranked by Charles with Newton's *Principia*, making a combination of Descartes's methods with those of his predecessors, added to geometry the beautiful theory of evolutes, which are the curves formed by the intersection of straight lines at right angles to a given curve; and he applied it not only to the pendulum, but to the theory of optics. Soon after (1686) Tschirnhausen published a wider conception of the generation of curves by straight lines. His famous caustics were made by the intersection of reflected or refracted rays of light; and he proposed other curves made by a pencil point stretching a thread whose ends were fastened, and which also wrapped and unwrapped from given curves. About the same time also De la Hire and Le Poivre invented, independently of each other,

modes of transforming one plane curve into another, by making the given curve a peculiar basis for the locus of a new curve. They thus transformed the circle into all the conic sections, without any reference to a cone. The great Newton also invented a means to the same end, so that the consideration of the ellipse and parabola became independent of that of any solid. Thus these methods, especially that of Le Poivre, anticipated descriptive geometry, and perhaps prepared the way for it. In 1700 Parent generalized the method of Descartes from representing a line to representing a curve surface by an equation between the distances of a point in the surface from three given planes, at right angles to each other; but this was not methodically arranged, and it was left for Clairaut, in 1731, to finish this great step. Meanwhile Newton's fluxions and Leibnitz's differential calculus had come into use, and Newton, Maclaurin, and Cotes had made the most exhaustive investigation into curves of the third degree, and many fine discoveries in regard to curves in general. The enthusiasm which Newton's example aroused in England and Scotland for pure geometry was followed by a lull of about a century, when Monge by his "Descriptive Geometry" gave the whole study new life. The essence of descriptive geometry lies in the transmutation of figures, the reduction of geometry of three dimensions to geometry in a plane. One beautiful example of this branch of science may be found in linear perspective, which simply projects the points of a solid upon a plane, by straight lines of light from the eye. Carnot, at the beginning of this century, in his "Geometry of Position" and "Theory of Transversals," also introduced valuable methods; in the first showing how to indicate the direction of lines more exactly by the use of positive and negative signs, and how to use the idea of motion more effectively than before in geometry; in the second introducing that general form of the theory of transversals, *i. e.*, of the intersections of a system of lines by one not belonging to the system, which Chasles employs so happily in his *Géométrie supérieure* (1852). This writer develops two principles in the correspondence of figures: one, the principle of duality, by which for a given figure a second is found such that points, planes, and straight lines in one correspond to planes, points, and lines in the other; the second, the principle of homography, by which for any figure a second is drawn such that points, planes, and lines in one correspond to points, planes, and lines in the other; the utility of each being to transfer the demonstrations of truth in one figure to the problems of another figure. We have alluded to the difficulty of appreciating the value of some of the new methods of treating geometry which have been discovered or invented in recent times, more especially the "quaternions" of Sir W. R. Hamilton and the "doctrine of extension" of Dr. H. Grassmann.

From a somewhat protracted study of both systems, the present writer is satisfied that any attempt to give a condensed account of them would only serve to perplex the reader. Especially is it difficult to comprehend either system without a more than ordinary acquaintance with the history of mathematical science during the present century, and particularly with the efforts to give a geometrical interpretation of what are called in algebra imaginary quantities.—The beginner in geometry will find many text books, of which none is more popular than the "Elements of Geometry and Trigonometry," by Prof. Charles Davies, from the works of A. M. Legendre (New York, 1858). Much more condensed and suggestive is an "Elementary Treatise on Plane and Solid Geometry," by Prof. Benjamin Peirce (Boston, 1858). An easier treatise than either of these, by Prof. G. R. Perkins, has been published in New York. The true style of Greek geometry may be found in Playfair's "Euclid." For advanced studies the following works is recommended: "Modern Geometry" by Mulcahy (London, 1859), giving a summary of the new methods, but not employing analytical geometry; "Elementary Treatise on Plane and Spherical Trigonometry," and "Elementary Treatise on Curves, Functions, and Surfaces," by Benjamin Peirce (Boston, 1858), giving its most condensed form the necessary elementary knowledge of the notation of geometry, analytical geometry, and the "Analytical Geometry," by Chasles (New York, 1855), giving a more popular expression of the same knowledge; a "Treatise on Conic Sections, containing an Account of some of the most important Modern Methods," by G. Salmon (London, 1855); a "Treatise on the Geometry of Curves," by the same author; Sir Isaac Newton's *Enumeratio Linearum Tertiarum*; Sir W. R. Hamilton's "Lectures on Quaternions" (Dublin, 1853) and "Elements of Quaternions" (London, 1866); "An Elementary Treatise on Quaternions," by P. G. Lebesgue (Paris, 1867); Chasles's *Traité de géométrie supérieure* (Paris, 1852), *Mémoire de géométrie sur les propriétés géométriques des surfaces sphériques* (Brussels, 1831; so translated into English), and *Aperçu sur l'origine et le développement des méthodes de géométrie* (Brussels, 1837; translated into English, Halle, 1839; a work which repays a close study); Carnot's *Geométrie de position* (Paris, 1803), *De la corrélation des figures de géométrie* (1801), and *La relation qui existe entre les distances de cinq points quelconques d'un espace, suivi d'un essai sur la théorie des quaternions* (1806, and 4to, 1815); Monge's *Géométrie descriptive* (Paris, 7th ed., 1804), and *Application de l'algèbre à la géométrie descriptive* (Paris, 1804); and *Systematische Entwicklung der Grundsätze der geometrischen Gestalten von einer rücksichtung der Arbeiten* (Leipzig, 1804).

*ter über Porismen, projective Methoden, trie der Lage, Transversalen, Dualität Reciprocität*, by Steiner (Berlin, 1832); books of Plücker of great merit, the *Analytische geometrische Entwicklungen* (2 vols., 1828-'31), *System der analytischen Geometrie auf neue Betrachtungsweisen gegründet* (1, 1833), *Theorie der algebraischen Curven gegründet auf eine neue Behandlungsweise analytischen Geometrie* (Bonn, 1839), and *der Geometrie des Raumes in neuer analytischer Behandlungsweise* (2d ed., Düsseldorf, 1852); *Lehrbuch der Geometrie*, by Karl Leipsic, 1841); *Grundlinien der neueren Geometrie*, by Dr. Benjamin Witzschel (Leipzig, 1858); and *Die Ausdehnungslehre vollständig und in strenger Form bearbeitet*, by Hermann Grassmann (Berlin, 1862).

**GEORGE (Lewis) I.**, king of Great Britain and Ireland, first sovereign of the Hanoverian dynasty in Osnabrück, May 28, 1660, died at that place, June 10, 1727. He was the second son of the elector Ernest Augustus of Hanover and the electress Sophia, granddaughter of James I. In 1681 he went to England to give his addresses to the princess (afterward Queen Anne; but immediately upon landing received his father's orders not to proceed with business, and returning home, he married the following year his cousin Sophia, daughter of the duke of Celle. He fought in the armies of the empire against the Turks and the French, and succeeded to the electorate in 1698. In 1700 he led a force to the aid of the duke of Holstein against Denmark and Sweden, and raised the siege of Copenhagen. He held to the English alliance throughout the war of the Spanish succession, 1701-'13, commanded the imperial forces against the French; but he did not approve the treaty of Utrecht in 1713, standing out against the emperor till the peace of Rastadt in 1714.

By acts of convention and parliament in 1689 and 1701 the succession of the English crown had been fixed as follows: James II. and his son being excluded, the next heirs were 1, the princess Mary of Orange, eldest daughter of James II.; 2, the princess Anne of Denmark, his younger daughter; 3, William of Orange, son of Mary, eldest daughter of Charles II. After the decease of Mary and William without issue, the crown should descend to the princess Anne, and on her decease without issue to the heirs of William. In the failure of these heirs the succession was further limited to the electress Sophia of Hanover, passing to her nearer heirs who were Roman Catholics. A treaty of union with Scotland in 1707 secured the succession for the crown in Great Britain. The Hanoverian succession was secured by treaty with Holland in 1706, and in 1713, and by the treaty of Utrecht in 1713. The electress Sophia died May 28, 1714, and her son George Lewis became heir apparent, and succeeded Queen Anne at her death on Aug. 1 of the same year. In spite

of schemes to place upon the throne the son of James II., the accession of George I. was without disturbance. He arrived with his eldest son at Greenwich in September, and was crowned the next month. The ministers of Queen Anne, Bolingbroke, Oxford, and their associates, were impeached, and a whig ministry came into power, Viscount Townshend and Sir Robert Walpole being its most influential members. The opposition broke out into rebellion in Scotland and the north of England, but was overcome in the battle of Preston, Nov. 12-13, 1715; and although the pretender landed in Scotland in December, 1715, his presence did not strengthen his cause, and he soon fled. The leading rebels were captured, and some of them punished with severity. The dangers of this rebellion led to the repeal of the triennial act, and an act was passed allowing parliament to sit for seven years unless dissolved by the crown. On Jan. 4, 1717, a triple alliance was formed with France and Holland against Sweden and Russia. The Swedish ambassador was arrested, and among his papers were found evidences of a plot for an insurrection in England, and an invasion of Scotland by the king of Sweden. In the preparations for defence, jealousy of Sunderland led to a schism in the ministry, and Walpole and others resigned. Stanhope now took the lead of the ministry. In 1718 a quadruple alliance was formed with Holland, France, and the emperor. In the short war that followed Admiral Byng annihilated the Spanish fleet at Cape Passaro, Aug. 11. There had long been hostility between the king and the prince of Wales, on account of the prince's mother, the unhappy Sophia of Celle. This lady had been suspected of an intrigue with Count Königsmark, who suddenly disappeared and was supposed to have been assassinated, while the princess was divorced in 1694 and imprisoned from that time till her death in 1726. The prince of Wales was attached to his mother, and the enmity with his father broke out into open hostility at the end of 1717. The prince left St. James's palace, and his residence, Leicester house, became a rival court. An important event of 1718 was the passing of a bill for the relief of Protestant dissenters. At this time arose the financial enterprises which culminated in the South sea company, of which the king was elected governor. Among the companies of the time were many of real value, but the principle of financial combination was extravagantly overrated; and when in 1720 the great South sea bubble burst, the general panic was overwhelming. The ministry was held responsible, and it was even expected that the king would abdicate. Lord Stanhope, in replying to an attack in the house of lords, was seized with a fit and died; on the following day (Feb. 5, 1721) Craggs, secretary of state, died of the smallpox, and Sunderland left the treasury. Walpole came to the front again,

supported by a house of commons strongly whig. In 1722 a new Jacobite plot was formed, but was detected, and Bishop Atterbury was banished for complicity in it. A patent was granted to William Wood, a proprietor and renter of copper mines in England, enabling him to coin farthings and halfpence for Ireland. This lucrative privilege was secured through the duchess of Kendal, the king's mistress; Walpole guarded against fraud, and Sir Isaac Newton, as master of the mint, approved the contract; but the issue caused immense disturbance in Ireland. Dean Swift wrote a pamphlet which raised a furious popular clamor, and the patent had to be withdrawn. In 1723 the *regium donum*, the grant to Presbyterians and other dissenters, was increased, and in 1724 the king founded professorships of modern history at Oxford and Cambridge. In 1725 the lord chancellor Macclesfield was impeached for malversation. There were many schemes for the overthrow of Walpole; but that sagacious statesman showed as much ability in disconcerting his private enemies as in his management of the national affairs. He kept the nation at peace, and secured a season of prosperity and progress. War was rekindled in 1725 by the alliance between the king of Spain and the emperor, and the treaty of Hanover between England, France, and Prussia, and subsequently Sweden. The siege of Gibraltar was begun by Spain in January, 1727; and a British fleet was sent to the West Indies, but accomplished nothing. Preliminary articles of peace were signed at Paris, May 31, 1727. In 1726 the King's unhappy wife died at her place of imprisonment. He is said to have been warned that he would survive her only a year. On June 3, 1727, immediately upon the agreement for peace, he set out for his beloved Hanover, accompanied by the duchess of Kendal and Lord Townshend. On the 10th he was taken with a fit in his carriage, and died before he could reach Osnabrück. He was buried in Hanover. He was a man of moderate faculties, a cruel husband and a bad father, with gross vices, yet by no means a bad sovereign. He did not attempt to interfere with the liberties of England; the ministry of Walpole was singularly able; and the policy of union with France, upheld by the same party which had been the war party of the preceding reign, was wise and statesmanlike beyond the time, it being for the interest of the nation as well as of the house of Hanover that the union between France and the house of Stuart should be broken up. By his queen Sophia of Celle George I. left a son, George Augustus, who succeeded him, and a daughter, Sophia Dorothea, who was married in 1706 to Frederick William I. of Prussia.

**GEORGE (Augustus) II.**, son of the preceding and of Sophia Dorothea, born in Hanover, Oct. 30, 1683, died in Kensington palace, Oct. 25, 1760. Little is known of his early history,

except that he was neglected by his father, and was brought up by his grandmother, the electress Sophia. He visited Holland in 1699, and in 1705 married Wilhelmina Dorothea Carolina, daughter of the margrave of Brandenburg-Anspach, a woman of marked character and superior talent. The next year he was made a peer of England, his chief title being duke of Cambridge, with precedence over the peers. He made the campaign of 1708 under the duke of Marlborough, and conducted himself with great bravery at the battle of Oudenarde, having his horse shot under him. In the opposite ranks, and showing equal valor, was the pretender, son of James II. He accompanied his father to England in 1714, and was proclaimed prince of Wales on Sept. 22. The quarrel between father and son broke out soon, and they hated each other cordially. The prince had been preferred by the electress Sophia to her own son, and was attached to his mother, causes that sufficed to increase his fatal original dislike of him. He was, moreover, upon as an instrument of politics against his father. The king also married a princess of Wales, and was jealous of her popularity. So vindictive was his feeling, he entertained a proposition, made by Berkeley, to carry off the prince to America, there to be so disposed of as never to be seen to his father again. When the prince fled from James's palace, at the close of 1717, he sought to deprive him of all control over his children; and the matter being referred to judges, 10 of the 12 decided in favor of the king. A sort of reconciliation was effected through Walpole's influence. When he succeeded the throne, George II. endeavored to transfer power to the hands of Sir Robert Compton, but his incapacity was so great that Walpole retained his place, the measure as he was supported by Queen Caroline. His coronation took place Oct. 11, 1727. The history of the first 14 years of the reign of George II. is that of the struggle of the king against opposition, the fiercest civil war known, unstained by blood, that has ever been known. The hopes that had been kindled of Walpole's overthrow as a consequence of the death of George I. had been disappointed, and that great minister's power remained on a firm basis. The king's weakness was an overwhelming minority. The king soon became strictly loyal, and his minister both on personal and political grounds. The royal avarice was generally disapproved, and was consulted by the minister. The king supported the latter in all his measures, but the support he received from his wife, who governed her husband with a firm hand, it, was of greater importance. George II. was as fond of Hanover as his father had been, and visited it often, to the disgust of his subjects. He hated his son Frederick, prince of Wales, as bitterly as he had hated his father, and the

gs in that respect. Frederick was not ed to visit England till 1728. The prince ore the king's parsimony and harsh treat- without complaint, and perhaps would done so to the last if it had not been for terest of the opposition to make him ac- ted with his political importance, and to im to resentment, because the king sup- l Walpole personally. The first great act reign was the treaty of Seville, concluded 29, between England, France, Spain, and ad, which was very advantageous to Eng- and by which Spain silently acquiesced English possession of Gibraltar. Walpole elled with his colleague Townshend in and the latter resigned office and retired ther from public life. Walpole was su- in the cabinet, and appears to have been ed to make some improvements in the and to correct abuses; but the virulence which all his measures were opposed in ment compelled him to be cautious. In and 1730 a committee of parliament in- ated the condition of prisons, and secured important reforms. In 1731 the use of in the courts of justice was discontinued, English substituted. The sinking fund, Walpole himself had aided to establish, o encroached upon that it soon ceased to any value. The great contest on the ex- ession was the most remarkable incident first half of the reign. The mere report intention to introduce a scheme of gen- xercise caused alarm, and the opposition, had been reduced very low, immediately o vigorous. The battle was fought with and courage on both sides, and though ne of its stages the ministerial majorities 60, they finally fell to 16, in a house of ons which had given Walpole almost 200 ity on other questions. The bill was then rawn, greatly to the satisfaction of the . The king was as much beaten as the er, and they revenged themselves by dis- g from office, or from sinecure places, a r of distinguished noblemen who had prominent in opposing the measure, the of whom was Lord Chesterfield. A new d broke out in Europe in 1733 in regard Polish succession. Walpole maintained utrality of England even in spite of the preference for war, and finally won the o his policy; and under the mediation land peace was concluded in 1735. The on of 1734 resulted in the return of a Walpolian majority. The opposition : the repeal of the test act, and were y 128 majority. The gin act, which : to do something to lessen drunkenness, ssed in 1736. The prince of Wales was d in 1736, and the question of his income d the opposition means to annoy the ry, and caused the quarrel between father n to become bitterer than ever. At the of his first child the prince left Hampton and took up his residence at Norfolk house.

The queen died in 1737, recommending her hus- band to Walpole with her last breath. In 1738 a son (afterward George III.) was born to the prince of Wales; and about this time the king gave notice that no visitor of the prince should be admitted to the court of St. James's. The opposition gathered more and more about the prince, and William Pitt became one of the gentlemen of his bedchamber. The opposition endeavored to have the army reduced in 1738, but failed. They then assailed the ministry because of its indifference to the outrages perpetrated by the Spaniards in America on Englishmen there trading. An arrangement made with Spain was unpopular. Pitt's fame may be dated from his speech against it. The ministerial majority was greatly reduced, but the minister was saved by the folly of his enemies, a number of whom seceded. The troubles with Spain went on, and war was declared against that country, Oct. 19, 1739. The ministerial strength now diminished, and the hopes of the Jacobites revived. The war was by no means brilliantly conducted. Anson's cruise in the Pacific and Indian seas revived the recollections of the Elizabethan age, and Vernon took Portobello; but the English failed at Cartagena, and also at Santiago de Cuba. The war of the Austrian succession began soon after, and England was drawn into it. Parliament was dissolved, and the new elections took place under circumstances unfavorable to Walpole. When parliament assembled, the opposition found themselves in a majority, and after a hard battle Walpole gave way, much to the grief of the king, who continued to take his advice to the last days of his life. Sir Robert was created earl of Orford, and the attempts made to prosecute him fell through. Lord Wilmington became premier, and Carteret secretary of state. Success was ruinous to the opposition, which showed it could not administer affairs, though so eloquent in fault-finding. The public was greatly disappointed, and the refusal of the victors to repeal the septennial act, which had been the object of their especial indignation when out of office, caused much disgust. England had now become actively engaged in the Austrian war, supporting the settlement called the pragmatic sanction, by which the Austrian succession devolved upon the late emperor's eldest daughter, Maria Theresa of Hungary, while France and Spain maintained the claims of Charles Albert, elector of Bavaria. A large force was sent to Flanders, which did nothing. Some success was achieved by the navy, and a British squadron compelled Naples to observe neutrality. The king, brave and fond of military life, was desirous of placing himself at the head of an army, and a large German force was taken into English pay. This added to the hatred of Hanover already felt in England. The king joined the allied army in June, 1743, and a few days later was fought the battle of Dettingen, in which the French were beaten, the monarch showing much courage. The death of

Lord Wilmington led to Henry Pelham's elevation to the premiership, the king acting under the advice of Walpole. Carteret continued to manage foreign affairs, and was much liked by the king. The Hanoverian policy was still vigorously opposed, but the resolute conduct of France, the fear of invasion, and the revival of the Jacobite party, caused some remission of party feeling, and the adoption of strong measures by government, the whigs of all views uniting in their support. The French government called Charles Edward Stuart to France, and extensive preparations were made to invade England, which failed through the occurrence of a storm, the fleet being destroyed or dispersed, February, 1744. War was declared against France a few weeks later, but little success attended it, and Carteret, now Earl Granville, was compelled to leave the ministry. Pelham forced the king to admit Chesterfield and some others of the old opposition to office, and Pitt gave his support to the government. The Hanoverian policy was kept up despite these changes, and England entered on an extensive system of German subsidies. Great preparations for the campaign of 1745 were made, but with no gain to England. The allies, commanded by the earl of Cumberland, were beaten by the French at Fontenoy. Charles Edward landed in Scotland, was joined by many highlanders and others, and, after occupying much of the ancient kingdom of his race, marched into England as far as Derby, when his leading supporters compelled him to retrace his steps. He was proclaimed at Perth and at Edinburgh. He won the battle of Gladsmuir or Preston Pans, and if he had pressed forward to London the capital would probably have fallen into his hands. George II., though very brave, and prepared to place himself at the head of his guards for a last fight, made preparations to fly. The rebels defeated the royal troops at Falkirk, but three months later their army was annihilated at Culloden (April 16, 1746). From that time dates the extinction of the Stuart party. The rest of the war was inglorious, and it was terminated by the treaty of Aix-la-Chapelle in 1748. For some years there was but little political discussion, and the opposition dwindled into a small faction, headed by the prince of Wales, which became extinct soon after his death in 1751. Private bills excited more interest in parliament than public ones. An increase in the stringency of the mutiny bill, and the passage of a regency bill, caused some discussion. The reformation of the calendar was effected by statute in 1751, providing that the year should commence on January 1 instead of March 25, and 11 days be dropped out of the month of September, 1752, thus bringing the year in accordance with the Gregorian calendar. The bill for the naturalization of the Jews, passed in 1753, though one of the most creditable acts of English legislation, caused so much popular excitement that it was immediately

repealed. In the same year was passed marriage act, requiring the publication of banns and a proper license, which was exceedingly unpopular, but is thought to have been a great blessing to the nation. The king died March 6, 1754, and was succeeded by his brother, the duke of Newcastle, who found himself compelled to share power with his first ally was Henry Fox, afterwards Lord Holland, and at a later day William Pitt. In 1754 the French aggressions in America came troublesome, and in July, 1755, occurred Braddock's defeat at Fort Duquesne. A seven years' war began in 1756, and England was involved in a contest of the severest character with France, while at the same time she was the ally of Prussia, which was at war with the empire, France, Russia, and other powers. The contest extended over the world and was marked by great actions in Europe, North America, and in the East Indies. The early part of the war was inglorious to England. In June Calcutta was taken by Mir Jafar Dowlah, and his prisoners were confined in the Black Hole. But shortly after the formation of the Pitt and Newcastle ministry in 1757, the genius of Pitt changed the face of the contest, and the English were triumphant in every quarter. Ample subsidies were furnished to Frederick of Prussia, so that he was enabled to make head against the coalition formed for his overthrow. An English and German army defeated the French in Germany, at Crefeld, Minden, and elsewhere. In North America was the scene of great actions, which ended in the expulsion of the French. An expedition to France, renewed, inflicted considerable damage on the country, destroying, among other things, the works at Cherbourg. The success of Clive at the foundation of the British Indian empire. Senegal and Goree were conquered; the victory of Admiral Hawke over the French in the naval battle of Quiberon, established British supremacy on the ocean. Never before had England stood so high as she stood in the midst of these successes, forming a striking contrast to most of his reign. George II. suddenly died at the age of 77. He was a man of ordinary character, and never popular with his English subjects; he governed constitutionally, and in his reign liberal polity was established, and the trial system of England was introduced.

**GEORGE (WILLIAM) FIFTH**, king of Great Britain, the preceding, and son of Frederick, prince of Wales, and of Augusta of Saxe-Gotha, born June 4, 1738, died in Windsor castle, March 29, 1820. He was not likely to be successful in the court of his father, nor did he expect that parent improve his prospects in life. His mother confined him in a small circle, wishing to preserve him from the profligacy of the day, in which he was successful; but he was brought up as an art prince might have been trained.

apparent to the throne of a constitutionally governed state. His disposition was arbitrary and crafty, and the whole of his long reign, until he lost his intellect, was passed in a continual combat against liberal ideas and institutions. At first he was popular. Young, a native of the country, and but little known to the people, his accession (Oct. 25, 1760) was hailed with loud rejoicings. His first speech in parliament contained a sentence, originated by himself, expressing pride in his English birth and confidence in the people, which excited great enthusiasm. He married, Sept. 8, 1761, the sister of the duke of Mecklenburg-Strelitz, Charlotte Sophia, who shared his throne for 57 years, and bore him 15 children, all but two of whom grew up. The fact that he had offered himself in 1761 to Lady Sarah Lennox seems to be proved by the statement of her brother-in-law, the first Lord Holland, and her son, Capt. Henry Napier, contained in "Holland House," by Princess Marie Liechtenstein (London, 1873). The new king was resolved upon being a king in fact as well as in name. To afford an opportunity to attempt the inauguration of the new system, it was necessary that peace should be restored, though the war was very popular, and Pitt, the war minister, was at the height of his power. The earl of Bute, long connected with the king's father and mother, was introduced into the cabinet, and ultimately became premier, and put an end to the war, though not until a new war had been made in consequence of Spain having joined France. When the family compact was made between France and Spain, Pitt was for anticipating the latter and commencing the war, but was overruled in the cabinet, where almost every man hated him because of his inordinate egotism and arrogance. He resigned his office Oct. 5, 1761; but the event showed the wisdom of his advice, for the conduct of Spain was such that England was compelled to declare war against her, Jan. 4, 1762. This war was a series of successes on the part of England. Havana was captured with a large part of the island of Cuba, the Philippines were reduced, treasure ships of immense value were taken from the Spaniards, and the naval and colonial supremacy of England was established. The effect was to make the premier more determined than ever upon peace, which was finally brought about at Paris in 1763, on terms that were honorable to England, though party spirit caused them to be denounced as treacherous, insecure, and disgraceful. The king became unpopular, and the minister was the object of violence. Lord Bute resigned in April, and was succeeded by George Grenville, whose administration commenced with the famous contest with Wilkes and the "North Briton." The restoration of peace enabled the king to seek the development of his political plans, and for many years he was engaged in a warfare against those principles to uphold which his house had been called to the British throne.

While George Grenville was minister, in 1765, the stamp act was passed, which threw the North American colonies into a blaze, and was the first in that series of acts which in their entirety make up the American revolution. The same year the first indications appeared of that mental malady which clouded the king's latter days. In July the Grenville ministry was dismissed, and the new ministry of Rockingham repealed the stamp act. In 1766 Pitt was made earl of Chatham, and formed a new ministry; and during this administration the taxation was renewed which ultimately led to American independence, although Chatham had little or nothing to do with this measure. He resigned in October, 1768. In 1769 appeared the famous letters of Junius attacking the policy of the ministry, and especially the duke of Grafton, who resigned in January, 1770, and Lord North, who had been chancellor of the exchequer, became premier, and held the place for 12 years. The modern tory party dates from that time as a powerful and efficient organization. The king ruled as well as reigned, and the attacks on American liberty were his acts, the guilt of the minister consisting in his being the tool, against his own convictions, of a master who was not always in possession of his reason. The year 1771 is memorable for the successful assertion by the newspaper press of the right of reporting the debates of parliament. The printer of the debates was arrested on the king's proclamation, but released by the London magistrates. In 1772 the king's message, provoked by the marriage of his brother in a manner he did not approve, secured the passage of the act, still in force, making the sovereign's consent necessary to marriages in the royal family. The American war began in the spring of 1775, and for seven years the most desperate efforts were made to conquer the colonies, which in 1776 declared themselves independent. Besides large bodies of English troops, and tories and Indians recruited in America, thousands of German mercenaries were employed in the war, which was marked by just enough of success to encourage the king to persevere. Gradually other countries were drawn into the contest, until it had assumed a European character. War between France and England began in 1778, and Spain and Holland were soon ranked among England's active enemies. The northern powers formed the armed neutrality. The combined fleets of France and Spain obtained command even of the English channel. Gibraltar was beleaguered by an immense fleet. Lord Chatham urged a conciliatory policy with the Americans in 1777. The same year Burgoyne's army surrendered, and four years later Cornwallis capitulated. The fortunes of England were never before so low; and though the successful defence of Gibraltar, and the naval victory won by Rodney over De Grasse, closed the war with some flashes of glory, the contrast between the state of things then and

20 years before was most humiliating to all reflecting Englishmen. The king was compelled to submit to a whig ministry, headed by the marquis of Rockingham and Charles James Fox (March, 1782). Lord Rockingham's death (July 1) caused the new ministry to fall to pieces, and power passed into the hands of the earl of Shelburne and the younger William Pitt. American independence was acknowledged, and peace restored, though the king was even then resolute to continue the contest, and talked of retiring to Hanover because of the coercion to which he was subjected. The Shelburne ministry was driven from power by the famous coalition of the Foxite whigs with the tories who followed Lord North (April, 1783). The king hated this ministry intensely, and talked of going to Hanover more than ever, and probably refrained from going because of the hint that while it would be easy to reach that country, it would not be so easy to get back to England. His submission was short-lived. The coalition broke down in an attempt to put a stop to the misgovernment of India. Its India bill passed the commons, but was thrown out by the lords in consequence of royal influence having been brought to bear on the minds of some of the peers. The king then dismissed the ministry, and placed Pitt at the head of his councils (December). After the new ministry had carried on a conflict with the coalition party in the commons until the latter had lost its majority, parliament was dissolved, and in the elections that followed the coalition was annihilated. The king, with the Pitt ministry, was now as popular as formerly he had been odious, and the tory party commenced a reign of nearly half a century. The prince of Wales was now of age. His loose life was all the more distasteful to the king because his associates were mostly whigs. As George I. had hated his eldest son, and George II. followed his father's example, so did George III. hate the heir apparent. Public affairs, however, went on smoothly, save that the impeachment of Hastings, who was patronized by the king, was brought about by the aid of Pitt. In August, 1786, an attempt upon the king's life was made by an insane woman named Margaret Nicholson. The labors of John Howard had led to legislation for prison reform. Various expedients were tried, and in 1787 the first convicts were transported to New South Wales. In 1788 the king was severely assailed by that illness which finally rendered him incapable of attending to business. A fierce struggle was commenced between parties, the object of the whigs being to have the prince of Wales made king under the title of regent should the royal illness continue, while the tories were determined to abridge materially the powers of the regent. The recovery of the king put an end to the contest, and was the subject of great national rejoicing. Immediately afterward occurred the commencement of the French revolution, which arrested his attention; and

that great movement determined of its issue. In 1793, having ing out of the war with France, and taking place with Russia, the object being the conquest of Turkey by the English. Opposition rallied and Turkey was saved. Another dispute with Spain, but did not lead to war. With revolutionary France began though the English maintained their character, defeating the French on June 1, 1794, at the Nile on Oct. 1, 1797, elsewhere, the Spaniards at Cape St. Feb. 14, 1797, and the Dutch Oct. 11, their military character was by its events. The most important was maintained at home, and the necessity of English juries prevented the ment of as complete a reign of terror in Britain as existed in France. The king was goaded into rebellion, which was supported by measures as cruel and bloody as any treated by the French republicans in La Vendée and Brittany. The union between Great Britain and Ireland was effected in 1800, the parliament of the latter ceasing to exist. France was allowed to send 100 members of commons and 80 representative members to the imperial parliament. Peace was made with France in 1802, though the king's wishes, his opinion being always in favor of bloodshed, unless his enemy should conditionally submit. The French had driven the British out of Egypt, and Malta captured in 1800. The peace was but a hollow truce. The refusal of the English to give up the renewal of the war in 1803, the ministry had broken down in 1801, the question of peace with France was possibly because of the king's bigotry, his relief to the Catholics, though it had been understood that it was to be granted on the conditions of the Irish union. Pitt became premier, and kept office until after the renewal of the war, when he returned to office. The threats of Napoleon to invade England, and the preparations he made for that purpose, caused the king to rally around the throne. The force was on foot, of 100,000 volunteers, while the navy was being built up. Spain was drawn into the war in 1808, and their united fleets were destroyed in Nelson's victory at Trafalgar (Oct. 21, 1805), which made England irresistible. The king settled the invasion question. For some time the king's influence in England was chiefly confined to the navy, though she assisted with money. Ships fitted out were sent to the north of Europe, her efforts were not accomplished north of Europe, until the breaking out of the war in 1808 that, under the

Wellesley, they performed anything worthy of the high name of their country. Pitt died in 1806, and the government passed into the hands of a coalition ministry, of which Lord Grenville and Mr. Fox were the chiefs. The object of the latter was the restoration of peace with France, but he died before anything could be done. The coalition endeavored to grant some relief to the Catholics, but the king got rid of it, and a ministry of tories was formed, headed by the duke of Portland (end of March, 1807). This ministry was probably the worst England ever had, and though it succeeded in the attack on Denmark, taking possession of the Danish fleet, the immorality of that attack more than balanced its success. Operations in Spain and Portugal were badly conducted; and the Walcheren expedition in 1809, which might have struck a deadly blow at Napoleon's power while he was combating Austria on the Danube, was probably the worst managed undertaking even in English history. This failure led to the breaking up of the Portland ministry, for which the Perceval ministry was substituted, an improvement on its predecessor, inasmuch as Marquis Wellesley took the foreign office. The commencement of the 50th year of the king's reign, October, 1809, was observed as a jubilee. There was little occasion for rejoicing. The war had failed utterly on land; France ruled almost the whole of continental Europe; the disputes with the United States threatened to add a new enemy to those England already had; while the conduct of some of the king's sons was flagrantly profligate. His second son, the duke of York, was compelled to resign the post of commander-in-chief, in consequence of the exposures made by Mrs. Clarke. In 1810 died the princess Amelia, the king's youngest and favorite daughter, and the king suffered so much from anxiety during her illness that he lost his reason for ever. More than once he had been raving mad. The first indication of his disease appeared on the very day of the completion of the 50th year of his reign, Oct. 25, 1810. His reign ceased in fact from that date, although in law it lasted more than nine years longer. The prince of Wales became prince regent by act of parliament on Feb. 5, 1811. The national events of the regency will be found under the title GEORGE IV. The care of the king's person was given first to the queen, and in 1819 to the duke of York. To his early education George III. owed a want of frankness and a moodiness when angry which did him much harm. But though he began his reign ignorant and ill educated, he learned much, and his last years of rule were as popular as the first had been unpopular. His original purpose to make himself an arbitrary monarch yielded to the rebuffs of his many defeats, and his personal morality and manly integrity and piety caused him to be respected and even beloved. A weak man naturally, and perhaps never strictly sane, he reigned

50 years, and left a memory in refreshing contrast with that of his immoral and un-English predecessors.

GEORGE (Augustus Frederick) IV., son of the preceding and of Queen Charlotte, born Aug. 12, 1762, died June 26, 1830. He was educated with great care, and closely restrained until 18 years of age, when he commenced a career of extravagance and profligacy that contrasted painfully with the upright life of his father. He early formed a connection with Mrs. Mary Robinson, an actress, and the wife of an attorney, who afterward became well known from her novels, verses, and autobiography. He became intimate with Fox, Sheridan, and other whig leaders, who were his companions in dissipation, and whose politics he adopted, in open opposition to his father. In 1783 his friends came into power as the famous coalition ministry, and on Nov. 11 he took his seat in the house of lords as duke of Cornwall, and as a supporter of the new administration, while they immediately demanded for him an augmented establishment and allowance, and Carlton house was assigned to him as a residence. When his friends fell from office he stood by them, and tried to restore them. In 1786 the debts of the prince were brought before parliament by Sheridan, but the king would not sanction a bill of relief. In the preceding year the prince had privately married Mrs. Fitzherbert. There is no doubt about the marriage, but it was illegal as being without the consent of the king; and Mrs. Fitzherbert being a Roman Catholic, the marriage, if valid, would have excluded the prince from the succession. When it was referred to in the debate on the prince's debts, Fox denied it, as he said, by the highest authority. In 1791 a difference arose between the prince and his sporting companions, and he sold his horses, shut up Carlton house, and devoted himself to the payment of his creditors, and in a speech in the house of lords separated himself from his old political friends. In 1795 he espoused his cousin, Caroline of Brunswick, in order to get his debts paid. After they had lived together for a year, during which their only child, the princess Charlotte, was born, they separated by common consent. Anxious for a complete divorce, the prince endeavored to prove his wife unfaithful. At this time he had returned to associations with Fox and his old friends, and was made a rallying centre by the whigs, while the tories naturally clung to the princess, who had the sympathy of the king. Under these circumstances took place the first investigation by parliament into her conduct. The main decisions of the investigation, which alone were made public, acquitted the princess fully, although the matter was made a subject of political dispute. It seems that at most she was guilty while in England only of imprudent acts, and her father-in-law always protected her, not only because he had caused the marriage, but because he hated her hus-

band. It was not until he became regent in 1811 that the prince of Wales assumed political importance, and he then gave himself up to the Tories. The years 1810 and 1811 were the period of Napoleon's greatest power. By conquest or by alliance continental Europe was under his control, although Sicily and Portugal were under the protection of England. In 1811 coolness arose between Napoleon and the czar Alexander. Early in 1812 Sweden became allied with Russia in resistance. The memorable Russian campaign followed. Wellington had taken Badajoz and Ciudad Rodrigo, and won the battle of Salamanca, and England rejected Napoleon's overtures for peace. War broke out this year with the United States, and success at first attended the English arms on the borders of Canada, while the frigate *United States* captured the British frigate *Macedonian*. In 1813 the war continued with varying fortune in America, and Wellington entered France in October. Napoleon was driven by the discontent at home to the campaign of 1814, beginning in January; but while by a bold movement he placed himself in the rear of his allied enemies, the latter marched upon Paris, which they entered March 31, and Napoleon abdicated and was taken to Elba. In America the city of Washington was taken, Aug. 24, but peace was signed with the United States at Ghent, Dec. 24. On March 1, 1815, Napoleon landed at Cannes, and an army was at once formed to oppose him in the Netherlands, of which Wellington took command on April 5. The victory of Waterloo, June 18, made England the most important power of Europe. The only wars of England now were in India, while the attention of the country was mainly given to the development of home industry and the agitation for parliamentary reform. An attempt was made in 1817 to assassinate the prince, and there was much discontent at his extravagance and vice. His daughter, the princess Charlotte, died in 1817. He became king, Jan. 29, 1820. The Cato street conspiracy for the assassination of the ministry absorbed attention at the beginning of his reign. The king soon commenced an open persecution of his wife which agitated the whole country. A bill of pains and penalties was introduced into the house of lords, charging the queen with adultery. The trial lasted for many weeks, and the bill passed to a third reading Nov. 10; but the majority for it was so small and public opinion so decidedly pronounced against the prosecution, that the government withdrew it. Nominally victorious, the queen was really beaten, and died of chagrin in less than a year. The king visited Ireland, Scotland, and Hanover, and apparently was popular. He was, however, greatly perplexed by politics. The progress of liberal opinions was making itself felt in England, and the ministry had to go with the world. Castlereagh's suicide and Canning's promotion were

sources of much trouble to him. The policy of Canning, decidedly opposed to policy of the holy alliance, was not so tasteful to him. When a French minister, at bidding of the holy alliance, entered England to restore absolutism (1823), England was hardly moved, and probably nothing but internal considerations prevented war with France. When Portugal appealed for English aid against Spain, that aid was promptly given. The independence of the Spanish American colonies was effectually promoted. The Greek revolution added to the interest which the king felt in foreign affairs, from classical traditions. Internal policy was liberalized. It led the way, through a tory minister, in reorganizing the criminal law; Huskisson's commercial ideas began to make head; Brough labored in the cause of education; the work of Catholic emancipation went forward. The year 1824 was a period of material prosperity, and was followed by a crash in 1825. The Burmese war, begun in 1824, ended in 1826 with a considerable cession to the British territory on the east coast of the bay of Bengal. Early in 1820 the duke of York, heir presumptive to the crown, died, and the title was transferred to the duke of Clarence, while his office of commander-in-chief was given to the duke of Wellington. Lord Liverpool, who had been minister since 1812, was incapable of paying further attention to business by the contest that followed for the premiership, and in the triumph of Canning, whereupon most of his associates resigned, and he was compelled to reconstruct the cabinet, which was on a liberal basis. He died, however, before he could accomplish anything. It was Lord Goderich, whose ministry lasted only a few months, during which the French fleet at Navarino was destroyed by the squadrons of England, France, and Russia, an event which the king called the "battle of Navarino." His speech at the opening of parliament in 1827. The ministry of Goderich was followed by Wellington, January, 1828, with the duke as first lord of the treasury and Peel as secretary. The return of the Tories to power was the signal for the revival of Catholic emancipation agitation, and the Catholics proved successful in 1829. The ministry had to choose between civil war and giving up their principles, and they made the sacrifice for them. The king, whose bigotry and unpopular ideas increased with his years, went out to the last against the current of opinion but was forced to give way. The king had previously been freed from these acts, noble though they were, by the ruin of the tory party, and so determined that it could not stand before the French revolution of 1830. He was soon after roused over by the French revolution of 1830. He was taken seriously ill early in the year, and died in midsummer. The duke of

was no flatterer, said of him after his death: "He was the most extraordinary compound of talent, wit, buffoonery, obstinacy, and good feeling—in short, a medley of the most opposite qualities, with a great preponderance of good—that I ever saw in any character in my life." His short reign had been remarkable for the advance made in liberal sentiments, and for the many practical reforms which it had witnessed; changes with which the sovereign had little to do. The England of 1830 bore but small resemblance to the England of 1820, and still less to that of 1810, when as regent George IV. had commenced the life of a sovereign. He left no legitimate children, and was succeeded by the duke of Clarence, third son of George III., as William IV.

**GEORGE I.**, king of Greece, born in Copenhagen, Dec. 24, 1845. He is the second son of Christian IX., king of Denmark, and brother of the princess of Wales. On June 6, 1868, he accepted the crown of Greece under the title of king of the Hellenes, relinquishing (Sept. 12) his rights of precedence in Denmark in favor of his younger brother Walde-mar, and was permitted to remain a Lutheran on condition of his children being brought up in the Greek faith. In 1866 his sister the princess Dagmar married the Russian czarévitch; and on Oct. 27, 1867, he married the grand duchess Olga, a daughter of the grand duke Constantine and a niece of the reigning czar, who has borne him a son (Aug. 2, 1868), the crown prince Constantine, duke of Sparta, and three other children. The principal event of his reign was the Cretan insurrection of 1866-'9, which led to serious complications with Turkey. (See GREECE.)

**GEORGE V.**, ex-king of Hanover, born in Berlin, May 27, 1819. He is a son of King Ernest Augustus and of a sister of Queen Louisa of Prussia, and married in 1843 the princess Mary of Saxe-Altenburg. Although an early weakness of the eyes ended in total blindness, he succeeded to the throne on the death of his father, Nov. 18, 1851, and soon created dissatisfaction by his affiliations with eccentric and unpopular courtiers, and by his ultra-conservative principles. Although he was a Protestant and a grand master of freemasons, his Roman Catholic minister Windthorst persuaded him to favor ultramontanes, while he engaged a tutor of the same faith for his elder son, and the ex-queen was reported in 1871 to have joined the church of Rome. His unstable policy resulted in a perpetual change of ministers, and in 1865 he restored a reactionary cabinet under Baumeister. Despite his relationship with the Prussian dynasty, and the remonstrances of his most influential favorite, the secretary general Zimmermann, he showed a deep aversion for Prussia; and as he ostentatiously sided with Austria at the outbreak of the war of 1866, his territory was invaded by the Prussians in June, and annexed by King William Sept. 20. He fled to

Vienna, where he kept up an incessant agitation against Prussia; and as even after he had agreed, in February, 1868, to accept 16,000,000 thalers as an indemnity for his lost kingdom, he persisted in his spiteful attitude, the Prussian government ordered (March 2) the provisional suspension of the payment of that amount.

**GEORGE**, prince of Denmark, born April 21, 1653, died Oct. 28, 1708. He was the second son of Frederick III. and Sophia of Lüneburg. On the death of his father in 1670 war was renewed with Sweden, and the prince took part in the campaign of his brother Christian V. against Charles XI., when the rival kings commanded and fought in person. On July 28, 1683, he married the princess Anne of England, second daughter of the duke of York, afterward James II. She bore him 17 children, all of whom died before their mother's accession to the throne. The prince was wholly devoid of talent, as of ambition. "I have tried him drunk," said Charles II., "and I have tried him sober; and drunk or sober, there is nothing in him." But he was brave, good-natured, and humane; taking no part in politics, and deserting his unhappy father-in-law in the hour of need, chiefly by the desire and after the example of his wife. He had been brought into the conspiracy through her subserviency to Churchill, the future duke of Marlborough, but his extreme insignificance rather excited the raillery of the king, even on this sad occasion. "After all," said James, hearing of his defection, "a good trooper would have been a greater loss." After the triumph of the prince and princess of Orange, Prince George was naturalized by act of parliament and created by the new king duke of Cumberland, in acknowledgment of his coöperation in the great measure which had been achieved. He accompanied the king to Ireland, and was present at the battle of the Boyne. On the accession of his wife, the "good Queen Anne," to the throne, in 1702, he was made lord high admiral of England. He had previously been invested with the title of generalissimo of all the queen's forces. As admiral he was assisted by a council consisting of four members. The legality of this board was much doubted, but parliament was so obsequious to the queen, that it was suffered to act without question.

**GEORGE I.** The patron saint of England, born, it is supposed, at Lydda or at Ramleh in Palestine in the latter half of the 3d century, said to have died in Nicomedia, April 23, 303. He appears to have been brought up in Cappadocia and to have embraced the military profession. It is the prevailing opinion of critics that Eusebius refers to him in his "Ecclesiastical History" (B. viii., c. 5), in speaking of "a man of no mean origin, but highly esteemed for his temporal dignities," who, when Diocletian's edict against the Christians was posted up in Nicomedia, "took it down and tore it in pieces." As the emperor was then present in the city, this deed of one of his officers en-

tailed on the offender the most cruel punishment. Reverence for the sufferer soon extended through Phœnicia, Palestine, and the whole East. A Greek inscription dated 346, on a very ancient church at Ezra, in Syria, mentions George as a holy martyr. Constantine the Great built a church over the tomb of the saint between Lydda and Ramleh; and the latter place, which claimed also to be his birthplace, was then called Georgia. In Constantinople a temple of Juno was converted by the same emperor into a church of St. George, to which his remains were translated. About the same time the name of "St. George's arm" was bestowed upon the Hellespont. In Rome, Palermo, and Naples churches also bore his name from a very early date. Queen Clotilde in 509 founded in his honor a convent at Chelles, and Clovis II. a convent at Baralle in Normandy. St. George was honored in England during the Anglo-Saxon period. Under Canute a monastery of St. George was founded at Thetford; St. George's, Southwark, was built a little later; and in the reign of the Conqueror there was a collegiate church of St. George in Oxford. England, Aragon, Portugal, and Genoa chose him as their patron. In 1222 a council held at Oxford ordained that St. George's day should be a national holiday. In 1470 Frederick of Austria instituted an order of knighthood called after him. About 1350 Edward III. made him the patron of the order of the garter. St. George is also the patron saint of Russia. St. George slaying the dragon was the cognizance of the grand dukes until the marriage of Ivan III. with the Greek princess Sophia, when the two-headed eagle, the Byzantine emblem, was adopted. It is still the emblem of Moscow. The Russian order of St. George was founded by Catharine II. in 1769. Besides the universal veneration in which he is held by Christians in the East, especially in Georgia, the Mohammedans revere him under the appellations of Ghergis and El-Khouder. The historian John Cantacuzenus enumerates several shrines erected by them in his honor; and Dean Stanley found a chapel on the seashore near Sarafend (ancient Sarepta) dedicated to El-Khouder. The George whose relics are shown in St. Germain-des-Prés, Paris, is a Syrian deacon martyred in Spain in 852; but his name is not in the Roman martyrology. The honor paid to St. George the martyr was sanctioned by Pope Gelasius I. in 494, in a council at Rome; but the "acts" were rejected as unworthy of credit. The crusaders found him honored by the Greeks with the surname of *Tropæophoros* or Victorious. He is generally represented, according to a comparatively modern legend, as slaying a dragon sent by a magician Athanasius to devour a princess Alexandria. This came from his being confounded with George of Cappadocia. II. Called the Fuller, the Arian, and George of Cappadocia, born in Epiphania, Cilicia, about 300, died in Alexandria

toward the close of 361. From the fuller's shop kept by his father, he is said by Ammianus to have raised himself to opulence by unworthy means. He collected a valuable library, became the leader of the Arians in Asia Minor, and through the influence of Constantius was chosen in 356 bishop of Alexandria while Athanasius was still living. He and his military supporters persecuted their religious opponents, pillaged the pagan temples, ruined commerce by monopolizing all trade, and proposed the impost of a heavy tax on households. Driven from the city by the revolted inhabitants, he was restored by military force; but on the accession of Julian he and his two principal followers were imprisoned by the pagans, and after 24 days were taken out and butchered. Gibbon and other writers confound George of Cappadocia with St. George the martyr; but Heylin and Milner, with whom Milman agrees, have shown them to be distinct personages.

**GEORGE, Enoch**, a bishop of the Methodist Episcopal church in the United States, born in Lancaster co., Va., in 1767 or 1768, died at Staunton, Va., Aug. 23, 1828. After preaching one year at the head waters of the Catawba and Broad rivers, in North Carolina, he was received into the conference on trial in 1770, and sent to Pamlico circuit. For four years he travelled over extensive circuits in the states of Virginia, North Carolina, South Carolina, and Georgia, when he was obliged to retire from active ministerial labor on account of physical debility. In 1799 he resumed the itinerant work in Rockingham Virginia. In 1800 he had charge of a district extending from Chesapeake the Alleghanies, but again his health failed, and for two years he taught a school at Chester, Va. In 1803 he resumed ministerial labors, acting as pastor of churches at Frederick, Alexandria, Montgomery, Baltimore, and as presiding elder of the Baltimore, Alexandria, and Georgetown districts, when he was elected to the episcopate, and continued to labor effectively in this office until the date of his death. He was remarkable for a peculiar and powerful style of preaching, and for great humility.

**GEORGE, Lake**, a picturesque sheet of water in Warren and Washington counties, N. H., 36 m. long from N. E. to S. W., 4 m. wide, and in some places discharging into Lake Champlain. It is remarkable for its pure water, its multitude of islands, supposed to correspond to the number of days of the year, and the steepness of its banks. Black mountain, on the E. face of the lake; and 12 m. from its mouth is a very steep rock, down which it flows when pursued by Indians during war, slid and landed safely.

far from this spot is the place where the English under Lord Howe landed previous to their attack on Fort Ticonderoga. The ruins of that fort can be seen at the E. end of the narrow channel through which the waters of Lake George are conveyed to Lake Champlain. Steamers ply upon the lake in summer, between Caldwell and Fort Ticonderoga, conveying large numbers of tourists attracted by its beautiful scenery. Caldwell, Bolton, and other places on its banks, are favorite summer resorts.—Lake George was discovered by the French from Canada early in the 17th century. Champlain knew of its existence in 1609, and saw it some time between that year and 1613. It was named by Father Jogues Lake St. Sacrement, from the festival of Corpus Christi on which he reached it, May 27, 1646. The English subsequently named it after King George II. By the Indians it was called Andiatarocte, or "the place where the lake closes." Cooper in his "Last of the Mohicans" called it Horicon, the name Horiconi being given on some old maps as that of an Indian tribe in the vicinity, probably by a misprint for Horicoui, that is, Iroquois. It bears a conspicuous place in American history. For more than a century it was a channel of communication between Canada and the settlements on the Hudson. In the French and Indian war it was repeatedly occupied by large armies, and was the scene of several battles. On Sept. 7, 1755, occurred engagements between the French and English, near the S. end of the lake, in which Col. Williams of Massachusetts, the founder of Williams college, was killed, Baron Dieskau, the French commander, severely wounded, and the French totally defeated. In 1757 Fort William Henry, at the same end of the lake, was besieged by the French general Montcalm, at the head of 10,000 men. The garrison, after a gallant defence, capitulated, and were barbarously massacred by the Indian allies of the French. In July, 1758, the army of Gen. Abercrombie, about 15,000 strong, passed up the lake in 1,000 boats, and attacked Ticonderoga without success. In July, 1759, Gen. Amherst with an almost equal force also traversed the lake and took Ticonderoga and Crown Point. The head of Lake George was the depot for the stores of the army of Gen. Burgoyne before he began his march to Saratoga.

**GEORGE OF TREBIZOND**, a Greek scholar, born in the island of Crete in 1396, died in Rome in 1486. He arrived in Italy in 1430 at the invitation of Francesco Barbaro, a noble Venetian, and became professor of Greek literature and philosophy at Venice. Pope Eugenius IV. invited him to Rome in the same capacity, and made him his secretary; and he was continued in these functions by Nicholas V. Though he was famous throughout Italy, some of his hasty translations of the Greek authors into Latin drew upon him attacks from Lorenzo Valla and Theodore Gaza, and his eulogies of Aristotle and attacks upon Plato pro-

voked the enmity of the Florentine admirers of Plato, and particularly of Cardinal Bessarion. His subsequent life was a series of disputes, and his writings are remarkable for violent personalities.

**GEORGES, Marguerite Joséphine**, mademoiselle, a French actress, born at Bayeux, Feb. 23, 1787, died at Passy, Jan. 12, 1867. She was a daughter of an actress and of a military tailor, Wemmer (long erroneously called Weymer). Some juvenile performances of hers at Amiens attracted the notice of the actress Raucourt, by whose influence she was brought to Paris and educated. Her imposing beauty and powerful acting produced a great sensation at her first appearance in 1802 as Clytemnestra; but as she desired to shine also in less austere characters, in which Mlle. Duchesnois excelled, a contest arose which subsequently resulted in her clandestine departure for Vienna, and soon afterward for Russia. The emperor Alexander I. became so infatuated with her that he would not consent to her returning to France, and in 1808 she played before him and Napoleon in Dresden and at Erfurt. Napoleon, one of her warmest admirers, and Hortense, one of her earliest patronesses, procured her readmission at the Théâtre Français in 1813, and the payment of her salary from the time of her entrance in 1803. Here Talma imparted great finish to her style; but in 1816 she again broke her engagement. Excepting occasional performances in England and Germany and the French provinces, she was subsequently connected with the Odéon and the Porte St. Martin theatres from 1821 to 1847, sustaining her reputation as a most impassioned and majestic tragedian. She gave farewell performances in 1849, and despite increasing stoniness she appeared once more in 1855. She was most admired as Semiramis, Merope, Dido, Agrippina, Lucrezia Borgia, Mary Tudor, and Catharine de' Medici. She received costly presents from emperors and princes, and from a host of other admirers and lovers; yet on retiring from the stage her poverty impelled her to become a teacher at the conservatory.

**GEORGETOWN**, an E. county of South Carolina, bordering on the Atlantic, bounded S. W. by Santee river and intersected by the Great Pedee, Black, and Waccamaw, which unite just above the seat of justice and enter the ocean through the estuary called Winyaw bay; area, 813 sq. m.; pop. in 1870, 16,161, of whom 13,388 were colored. The surface is level and partly occupied by marshes and pine forests. The soil is generally fertile. The chief productions in 1870 were 14,094 bushels of Indian corn, 7,644 of sweet potatoes, 5,324,970 lbs. of rice, and 61 bales of cotton. There were 4 manufactories of barrels and casks, 5 of tar and turpentine, 1 saw mill, and 1 planing mill. Capital, Georgetown.

**GEORGETOWN**. I. A port of entry of the District of Columbia, situated at the head of navigation on the left bank of the Potomac,

125 m. from its mouth, and  $2\frac{1}{2}$  m. N. W. of the capitol, Washington, from which it is separated by Rock creek, which is spanned by four handsome iron bridges; pop. in 1850, 8,366; in 1860, 8,733; in 1870, 11,384, of whom 3,217 were colored and 1,020 foreigners. On the north and west it is overlooked by heights, commanding a magnificent view of Washington and the Potomac, and a vast expanse of country, and crowned by villas and country seats. It is a quiet but thriving place, noted for its refined society and educational advantages. The custom house and post office building is near the centre. On the N. W. slope of the heights is Oak Hill cemetery, encompassed by an iron fence, and beautified by original forest trees; it was laid out in 1849. Extensive street improvements are in progress. The Chesapeake and Ohio canal has its terminus at Georgetown, where a branch is carried across the Potomac by an aqueduct 1,446 ft. long, and 36 ft. above the ordinary tide, over which is an elevated roadway. Georgetown is the only port of the District, and is connected by steamship lines with New York, Philadelphia, Boston, Baltimore, and Norfolk, and carries on a considerable coasting trade. The value of foreign commerce for the year ending June 30, 1873, was \$29,555. The canal furnishes excellent water power, which is utilized by a number of extensive flour mills, and brings down large quantities of bituminous coal from the Cumberland mines. The principal literary institution is Georgetown college, under the direction of the Jesuits, which was founded as a college in 1789 and chartered as a university in 1815. It consists of a classical, a medical, and a law department. The classical department has a senior division (corresponding to the ordinary college course), divided into four classes; a junior division, divided into two classes; and a preparatory department, with two classes; the whole covering seven years. There is also a post-graduate course of two years. Besides more than 3,000 volumes in the students' libraries, the college possesses a library of some 30,000 volumes, among which are many rare and curious works. There are 100 volumes printed between the years 1460 and 1520; three manuscripts anterior to the year 1400, and one of the year 1280. The faculty consists of the president and 20 professors and instructors. The number of students in 1872-'3 was 187, viz.: senior division, 53; junior division, 65; preparatory, 69. The number of graduates was 11. The medical department was organized in 1851, and a school of pharmacy has recently been established in connection with it, in which diplomas are given for proficiency. In 1872-'3 there were 10 professors and 56 students, of whom 24 graduated in medicine and one in pharmacy. The law department was established in 1870, and in 1872-'3 had 4 professors and 56 students, of whom 23 graduated. These two departments are in Washington. The college buildings, which are

spacious, are at the W. end of Georgetown and are surrounded by handsome grounds. Near the college is a convent of Visitation nuns, founded in 1799, and attached to the latter a female academy, with a library of 2,500 volumes. Georgetown institute is an English and classical school for boys. The whole number of private schools in 1872 was 21 (including 6 for secondary instruction), with 869 pupils. There were 4 public school houses and 17 separate schools, including 7 for colored children, having 19 teachers and an average attendance of 705 children. The principal charitable institutions are the aged women's home and the industrial home school for juvenile vagrants. There are a national bank, an insurance company, a weekly newspaper, a monthly periodical (published by the college students), and 13 churches.—Georgetown was laid out in pursuance of an act of the colonial government of Maryland dated June 3, 1751, and was incorporated as a city Dec. 23, 1789. The charter was abolished upon the organization of the territory of the District of Columbia in 1871, but the locality is still known as the "city of Georgetown." (See DISTRICT OF COLUMBIA.) II. A town, port of entry, and the capital of Georgetown co., South Carolina, situated on the W. shore of Winyaw bay, near the confluence of the Black and Great Pedee rivers, 15 m. from the sea and 110 m. E. S. E. of Columbia; pop. in 1870, 2,080, of whom 1,879 were colored. The entrance to the harbor is obstructed by a bar. The neighboring country produces large quantities of rice. The value of foreign commerce, consisting wholly of exports, for the year ending June 30, 1873, was \$64,537; entered, 6 vessels of 907 tons; cleared, 21 vessels of 3,813 tons. In the coastwise trade 80 vessels of 19,387 tons entered, and 14 vessels of 2,250 tons cleared. There were 7 sailing vessels of 767 tons, and 9 steamers of 773 tons belonging to the port. III. A town and the capital of Scott co., Kentucky, built on high ground in the midst of the fertile section known as the "blue grass region," on the North Elkhorn river, 17 m. E. of Frankfort; pop. in 1870, 1,570, of whom 728 were colored. It contains two factories, two banks, and a weekly newspaper. It is the seat of Georgetown college (Baptist), founded in 1822, occupying three large buildings, and having in 1873 8 professors, 135 students (41 preparatory), and a library of 7,000 volumes. The western Baptist theological institute, founded at Covington in 1840, was removed to Georgetown in 1854, and is conducted in connection with Georgetown college. In 1873 it had 2 professors and 24 students. Georgetown female seminary (Baptist) in 1873 had 7 instructors and 110 students. Warrendale female college (Reformed) had 4 instructors and 70 students.

GEORGETOWN (Dutch, *Stadbrook*), the capital of British Guiana, and of the county of Demerara, situated on the E. bank of Demerara

river, at its mouth, here about 1 m. wide; lat.  $30^{\circ} 21'$  and  $35^{\circ} N.$ , and lon.  $80^{\circ} 48'$  and  $85^{\circ} 40'$  W., having an extreme length N. and S. of 320 m., and an extreme breadth E. and W. of 254 m.; area, 58,000 sq. m. It is bounded N. by Tennessee and North Carolina, N. E. by South Carolina, from which it is separated by the Savannah river, E. by the Atlantic ocean, S. by Florida, and W. by Alabama, from which it is partly separated by the Chattahoochee river. It is divided into 136 counties, viz.: Appling, Baker, Baldwin, Banks, Bartow, Berrien, Bibb, Brooks, Bryan, Bullock, Burke, Butts, Calhoun, Camden, Campbell, Carroll, Catoosa, Charlton, Chatham, Chattahoochee, Chattooga, Cherokee, Clarke, Clay, Clayton, Clinch, Cobb, Coffee, Colquitt, Columbia, Coweta, Crawford, Dade, Dawson, Decatur, De Kalb, Dodge, Dooly, Dougherty, Douglas, Early, Echols, Effingham, Elbert, Emanuel, Fannin, Fayette, Floyd, Forsyth, Franklin, Fulton, Gilmer, Glascock, Glynn, Gordon, Greene, Gwinnett, Habersham, Hall, Hancock, Haralson, Harris, Hart, Heard, Henry, Houston, Irwin, Jackson, Jasper, Jefferson, Johnson, Jones, Laurens, Lee, Liberty, Lincoln, Lowndes, Lumpkin, Macon, Madison, Marion, McDuffie, McIntosh, Meriwether, Miller, Milton, Mitchell, Monroe, Montgomery, Morgan, Murray, Muscogee, Newton, Oglethorpe, Paulding, Pickens, Pierce, Pike, Polk, Pulaski, Putnam, Quitman, Rabun, Randolph, Richmond, Rockdale, Schley, Scriven, Spalding, Stewart, Sumter, Talbot, Taliaferro, Tatnall, Taylor, Telfair, Terrell, Thomas, Towns, Troup, Twiggs, Union, Upson, Walker, Walton, Ware, Warren, Washington, Wayne, Webster, White, Whitfield, Wilcox, Wilkes, Wilkinson, and Worth. The counties are subdivided into 1,186 militia districts, and contain 184 incorporated towns. There are eight cities, viz.: Savannah (pop. in 1870, 28,235), the chief port, on the river of

river, at its mouth, here about 1 m. wide; lat.  $30^{\circ} 21'$  and  $35^{\circ} N.$ , and lon.  $80^{\circ} 48'$  and  $85^{\circ} 40'$  W., having an extreme length N. and S. of 320 m., and an extreme breadth E. and W. of 254 m.; area, 58,000 sq. m. It is bounded N. by Tennessee and North Carolina, N. E. by South Carolina, from which it is separated by the Savannah river, E. by the Atlantic ocean, S. by Florida, and W. by Alabama, from which it is partly separated by the Chattahoochee river. It is divided into 136 counties, viz.: Appling, Baker, Baldwin, Banks, Bartow, Berrien, Bibb, Brooks, Bryan, Bullock, Burke, Butts, Calhoun, Camden, Campbell, Carroll, Catoosa, Charlton, Chatham, Chattahoochee, Chattooga, Cherokee, Clarke, Clay, Clayton, Clinch, Cobb, Coffee, Colquitt, Columbia, Coweta, Crawford, Dade, Dawson, Decatur, De Kalb, Dodge, Dooly, Dougherty, Douglas, Early, Echols, Effingham, Elbert, Emanuel, Fannin, Fayette, Floyd, Forsyth, Franklin, Fulton, Gilmer, Glascock, Glynn, Gordon, Greene, Gwinnett, Habersham, Hall, Hancock, Haralson, Harris, Hart, Heard, Henry, Houston, Irwin, Jackson, Jasper, Jefferson, Johnson, Jones, Laurens, Lee, Liberty, Lincoln, Lowndes, Lumpkin, Macon, Madison, Marion, McDuffie, McIntosh, Meriwether, Miller, Milton, Mitchell, Monroe, Montgomery, Morgan, Murray, Muscogee, Newton, Oglethorpe, Paulding, Pickens, Pierce, Pike, Polk, Pulaski, Putnam, Quitman, Rabun, Randolph, Richmond, Rockdale, Schley, Scriven, Spalding, Stewart, Sumter, Talbot, Taliaferro, Tatnall, Taylor, Telfair, Terrell, Thomas, Towns, Troup, Twiggs, Union, Upson, Walker, Walton, Ware, Warren, Washington, Wayne, Webster, White, Whitfield, Wilcox, Wilkes, Wilkinson, and Worth. State Seal of Georgia.

the same name, 18 m. from the sea; Atlanta (pop. 21,789), the capital, in the N. W. part of the state; Augusta (pop. 15,389), on the Sa-

vannah, 248 m. from its mouth; Macon (pop. 10,810); Columbus (7,401); Athens (4,251); Milledgeville (3,750), the former capital; and

Rome (2,748). Among the towns are Albany, Americus, Bainbridge, Brunswick, Cartersville, Corvinton, Cuthbert, Dalton, Dawson, Eatonton, Fort Valley, Griffin, La Grange, Marietta, Newnan, Thomasville, Valdosta, Washington, and West Point, having each more than 1,000 inhabitants.—The population of the state in 1790 and at subsequent decennial periods was as follows:

U. S. CENSUS	White	Free colored	Slave	Total
1790.....	52,446	898	29,244	82,588
1800.....	101,674	1,019	50,444	153,137
1810.....	145,414	1,401	103,217	249,032
1820.....	182,764	1,767	149,656	334,187
1830.....	234,406	2,474	217,281	454,161
1840.....	297,423	2,758	281,944	582,125
1850.....	351,572	2,981	381,642	736,195
1860.....	501,750	3,500	462,170	967,420
1870.....	635,726	3,642	545,142	1,184,510

Included in the last total are 1 Chinaman and 40 Indians. Georgia ranked 12th among the states in 1870 in total population, a gain since 1860 of 12 per cent.; 10th in the number of white inhabitants, gain 8.01 per cent.; and 1st in colored population, gain 17.06 per cent. There were 1,172,982 natives and 11,127 foreigners, 578,935 males and 605,154 females. Of the natives, 933,969 were born in the state, 54,937 in South Carolina, 26,858 in North Carolina, 19,034 in Virginia and West Virginia, 12,230 in Alabama, 9,394 in Tennessee, and 4,781 in Florida. There were 374,143 persons born in the state living in other states and territories. Of the foreigners, 5,093 were natives of Ireland, 2,761 of Germany, and 1,088 of England. Of the colored, 501,814 were blacks, and 43,328 mulattoes. The number of male citizens of the United States 21 years old and over was 234,919. There were 237,850 families, having an average of 4.98 persons to a family, and 236,436 dwellings, averaging 5.01 to a dwelling. There were 418,553 persons 10 years old and over unable to read, and 468,593 unable to write, of whom 343,637 were colored and 1,070 foreigners, 220,070 males and 248,523 females; 101,114 were between 10 and 15 years of age, 92,120 from 15 to 21, and 275,343 21 and over. Of the last number, 21,899 were white males and 100,551 colored males. The number of blind persons was 740; deaf and dumb, 326; insane, 634; idiots, 871; paupers, 1,816, of whom 507 were colored and 39 foreigners; persons convicted of crimes during the year, 1,775. There were 444,678 persons 10 years old and over engaged in occupations, viz.: 336,145 in agriculture, 64,083 in professional and personal services, 14,410 in trade and transportation, and 27,040 in manufactures and mining. Included in these numbers were 264,605 agricultural laborers, 70,468 farmers and planters, 953 clergymen, 37,027 domestic servants, 14,976 laborers, 851 lawyers, 1,537 physicians and surgeons, 2,223 teachers, 5,429 traders and dealers, 3,545 clerks, salesmen, &c.,

5,105 officials and employees of railroad companies, 1,279 carmen, draymen, &c., 1,292 blacksmiths, 1,375 boot and shoe makers, 1,095 masons and stone cutters, 4,723 carpenters and joiners, 2,519 cotton and woollen mill operatives, 1,200 millers, 1,215 saw-mill operatives, and 2,604 tailors, seamstresses, &c.—Georgia presents a great variety of surface. Along the coast and the Florida line it is low and swampy, while a little further back occur parallel ranges of sand hills, 40 or 50 ft. high. Near the E. corner is the Okefenokee swamp, or rather series of swamps, about 180 m. in circuit filled with pools and islands, covered with vines, big trees, and underwood, and teeming with alligators, lizards, and other reptiles. The elevation for 20 m. inland rarely exceeds 40 ft., and averages 10 to 12 ft. above the sea. Then the land suddenly rises by a terrace 70 ft. high, and this table land continues nearly level about 20 m. further inland, when another rise of 20 ft. leads to a third tract, which continues to ascend toward the north, till at Milledgeville, about 150 m. from the sea, the elevation is about 575 ft. From the central portion of the state the surface becomes more elevated, the hills increasing in size toward the north. The southern spurs of the Appalachians, which cross the N. portion of the state from N. E. to S. W., are reached in the Etowah hills of Bartow and Cherokee counties, and the Amicolola hills of Gilmer and Lumpkin; and the Blue Ridge, ranging with these between Lumpkin, White, and Habersham counties as far south, and Union and Towns on the north, constitutes the great watershed. These mountains attain an elevation of from 1,200 to 4,000 ft.—The coast of Georgia extends S. E. W. from Tybee sound to Cumberland sound, a distance of about 100 m., with a shore line estimated at 480 m. Though generally uniform as to contour, it is very irregularly indented, and is skirted by numerous low islands which extend parallel to the shores. The principal of these from N. to S. are Cabbage, Oseabaw, St. Catherine's, Sapelo, St. Simon's, Jekyll, and Cumberland. The inlets and sounds which divide the islands from one another and from the mainland are generally navigable, but too shoal to admit vessels of more than 100 tons. Vessels of larger dimensions can enter only four harbors: Savannah, Darien, Brunswick, and St. Mary's. The bar of the Tybee entrance of the Savannah has 19 ft. of water; that of the Sapelo entrance of the Altamaha, 14 ft.; that of St. Simon's sound (entrance of Brunswick harbor), 17 ft.; and that of St. Mary's river, 14 ft. These figures represent the least water in the channel ways at low water of mean tides; the mean rise of tides on this part of the coast varies from 7 ft. in the Savannah to 8-9 ft. in the St. Mary's.—The Savannah, the largest river of Georgia, and the boundary toward South Carolina, rises by two head streams, the Tugaloo and Keowee, in the Appalachian chain, and near the sources of the Tennessee and Missis-

see on the one side and of the Chattahoochee on the other. From the junction of these confluents (lat.  $34^{\circ} 28'$ ) the river has a S. S. E. course of 450 m. to the sea, which it meets near lat.  $32^{\circ}$  and lon.  $81^{\circ}$ . It is navigable for large ships to Savannah, 18 m., and for steamboats of 150 tons to Augusta, 230 m. further; and by means of a canal round the falls navigation for small steamboats is prolonged for 150 m. above. The Chattahoochee rises near the W. constituent of the Savannah, pursues at first a S. W. course, but at West Point (lat.  $32^{\circ} 52'$ ) on the Alabama line turns S. and enters Florida (lat.  $30^{\circ} 41'$ ) under the name of the Appalachicola. Its whole length to the gulf is about 550 m., and steamboats ascend it 300 m. to the falls at Columbus. Flint river rises in the hilly country S. of the Chattahoochee, and joins that river in the S. W. corner of the state after a course of 300 m.; it is navigable for steamboats to Albany. The Ochlockonee, Withlacoochee, and Allapaha drain the S. section of the state, and pass through Florida to the gulf of Mexico. The Withlacoochee and Allapaha by their junction in Florida form the Suwanee. Next to the Savannah, the Altamaha is the largest river falling into the Atlantic. It is formed by the junction of the Oconee and Ocmulgee, which rise in the hilly region S. of the Chattahoochee and flow for about 250 m. nearly parallel to each other, when the latter bends to the east and unites its waters with those of the former. The main river is navigable for sea-going vessels to Darien, and steamboats ascend the Ocmulgee to Macon and the Oconee to Milledgeville. The Ogeechee drains the country between the Savannah and Altamaha, and has a S. E. course of 200 m., with 30 or 40 m. of sloop navigation; its southern branch, the Cannouchee, is navigable for 50 m. The Santilla and St. Mary's drain the S. E. section of the state; both are navigable for sloops about 40 m., and for boats much further; the St. Mary's forms the boundary toward Florida. The N. and N. W. sections of the state are drained by the Tacoah, the Notley, and other tributaries of the Hiwassee; and by the Oostenaula and Etowah, which, uniting at Rome, form the Coosa, one of the tributaries of the Alabama. The Tallapoosa, also a tributary of the Alabama, has its sources in this state between the Coosa and Chattahoochee.—Georgia is naturally divided into two regions distinguished by their geological structure, as well as by their topography, climate, and vegetable productions. The line of the first falls which are met with in ascending the streams marks here, as well as further N., the ascent upon the platform of granitic and palæozoic rocks, which stretches on to the Appalachian mountains. This line crosses the central portion of the state from Augusta on the Savannah, by Macon on the Ocmulgee, to Columbus on the Chattahoochee. It is nearly parallel with the range of the Alleghanies, which crosses in a N. E. and S. W. direction

the northern portion of the state; but it is so distant from these mountains that the intervening hilly region of the metamorphic and lower Silurian rocks is here much broader than elsewhere along the eastern slopes of the Alleghanies. The width of the belt is not far from 150 m. On the south it is succeeded immediately by the lowest tertiary, the eocene, whose sands, clays, and calcareous and silicious strata are seen reposing upon the ancient metamorphic slates and gneiss along the line of contact with these. The cretaceous formation only intervenes from a point almost in the centre of the state, near Macon, gradually widening in its outspread toward the west and pushing the outcrop of the overlying eocene further to the south. The cretaceous group is also seen at a few isolated points rising through the tertiary near the Ogeechee river. S. of the line designated above, the whole country toward the gulf of Mexico and the Atlantic ocean is occupied by the eocene and the modern tertiaries of the coast; a belt wider even than that of the ancient formations of the N. half of the state. In the alluvium, which attains an elevation of only a few feet above the water, skeletons of the mastodon, mylodon, megatherium, an extinct species of elephant, and of the ox, have been found; and beneath the muddy peaty soil in which they lie the sands and clays are of the post-tertiary formation, containing fossil shells, all of the same species that now live in the neighboring salt water. In Bartow co. the limestones of the lower Silurian are met with just N. of the Etowah river, and the formation extends toward Tennessee, till in the N. E. corner of the state it is overlaid by later members of the palæozoic rocks, which finally are capped by the coal formation. Near the junction of the limestone with the metamorphic rocks immense deposits of iron ore are found, in the latter ranging N. E. from the S. E. corner of Bartow through Cherokee co. Gold was discovered in 1829 in Habersham co. It occurs in veins and alluvial deposits in almost every county N. of the central line of the state, the W. limit being the W. base of the mountains. The chief deposits are in a belt, 15 to 20 m. wide, extending across the state on the E. slope. The production from 1829 to 1838 is estimated at 800,000 ounces; from 1838 to 1849, at 200,000 ounces; and it has gradually diminished until in 1870 only five mines were in operation, the product being valued at \$29,780. The amount of gold deposited at the United States mint and branches, from Georgia, to June 30, 1873, was \$7,267,784 76. The copper veins worked in Polk co., Tenn., are traced across the line into Gilmer co. The other mineral productions of the state, except the limestones, and in the eocene region the marls and buhrstone of this formation, are of little importance.—Among objects of interest are the falls of Tallulah, in a branch of the Tugalo, in Habersham co.; Toccato falls in the same

stream, 185 ft. high; Amicolah falls in Lumpkin co., with a descent of 400 ft. in as many yards; Towaligo falls in Monroe co.; the falls in Rabun co., and a series of falls in the Hiawassee. Stone mountain in De Kalb co., 7 m. in circuit, and 2,220 ft. high, abounds in fine scenery, and Track rock and Pilot mountain (1,200 ft. high) in Union co. are worthy of mention. Niojack cave extends into the Raccoon mountains, near the N. W. extremity of the state, for several miles, with a portal 160 ft. wide and 60 ft. high, through which flows a stream, up which boats can pass for 3 m. to a cataract. In Hancock and Bartow cos. and near Macon are artificial mounds, containing ruins of fortifications, articles of pottery, and human remains.—In the low lands and swamps along the coast the climate is hot and unhealthy, malarious fevers being prevalent, while in the pine lands further back the air is salubrious. In the N. portion of the state the climate is cooler and healthful. The following table embodies the results of meteorological observations made at Augusta and Savannah, under the direction of the chief signal officer of the United States, for the year ending Sept. 30, 1872:

MONTHS.	MEAN THERMOMETER.		TOTAL RAINFALL, INCHES.		PREVAILING WIND.	
	Augusta.	Savannah.	Augusta.	Savannah.	Augusta.	Savannah.
October .....	66°	68°	1·62	3·55	S. E.	N. E.

Year .....	63·8	66·2	61·75	61·96	W.	S. W.

The number of deaths in 1870 was 13,606, including 3,923 from general diseases, 1,519 from diseases of the nervous system, 445 of the circulatory, 2,247 of the respiratory, 2,230 of the digestive, and 241 of the integumentary system; 741 deaths were caused by enteric, 405 by intermittent, and 300 by remittent fever, 875 by consumption, 248 by dropsy, 270 by measles, 145 by cerebro-spinal fever, 277 by encephalitis, 379 by meningitis, 116 by apoplexy, 165 by paralysis, 214 by convulsions, 356 by croup, 1,363 by pneumonia, 233 by hydrothorax, 239 by enteritis, 327 by dysentery, 448 by diarrhoea, 344 by cholera infantum, and 100 by ascites.—The soil of the coast islands is light and sandy, but productive of long-staple or “sea island” cotton. The mainland possesses a rich alluvial soil, producing corn and cotton, while the tide swamps of the rivers are fertile in rice. Back from the coast is a stretch of sandy land, chiefly valuable for its timber and naval stores, but capable of being made

productive. The S. W. portion of the state is light and sandy, but yields good crops of cotton, and the middle region, possessing a red loamy soil, produces cotton, corn, tobacco, &c. These two portions of the state have been much exhausted by unscientific cultivation. The N. region contains much fertile land, particularly in the valleys, yielding grain, fruits, potatoes, and other vegetables, but is not so well suited to cotton. Near the coast, the growth along the banks of the streams is of canes, cypress, *magnolia glauca* and *grandiflora*, gum of different species, including the liquidamber tree, oaks, tulip, ash, sweet bay, and many other genera; while back upon the sandy lands pines and scrub oaks are almost the only trees. Several species of palmetto give a tropical aspect to the sea islands, and the magnificent live oaks largely obtained in the vicinity of Brunswick furnish the most valuable ship timber grown in the United States. In 1870 Georgia produced more cotton than any other state except Mississippi; more rice than any other except South Carolina; and more sweet potatoes than any except North Carolina. The number of acres of improved farm land was 6,831,856; value of farms, \$94,559,468; of farming implements and machinery, \$4,614,701; wages paid during the year, including the value of board, \$19,787,086; estimated value of all farm productions, including betterments and additions to stock, \$80,390,228; value of orchard products, \$352,926; of produce of market gardens, \$193,266; of forest products, \$1,281,623; of home manufactures, \$1,113,000; of animals slaughtered, or sold for slaughter, \$6,854,382; of live stock, \$30,156,317. The productions were 308,890 bushels of spring and 1,818,127 of winter wheat, 82,549 of rye, 17,646,459 of Indian corn, 1,904,601 of oats, 3,600 of barley, 402 of buckwheat, 410,020 of peas and beans, 197,101 of Irish potatoes, 2,621,502 of sweet potatoes, 148 of clover and 540 of grass seed, 48 of flaxseed, 22,277,380 lbs of rice, 288,596 of tobacco, 846,947 of wool, 4,499,572 of butter, 4,292 of cheese, 2 of hops, 983 of flax, 14 of silk cocoons, 31,233 of wax, 610,877 of honey, 473,934 bales of cotton, 21,927 gallons of wine, 109,139 of milk sold, 553,192 of cane and 374,027 of sorghum molasses, 644 hogsheads of sugar, and 10,516 tons of hay. The live stock consisted of 81,777 horses, 87,426 mules and asses, 231,310 milk cows, 54,332 working oxen, 412,261 other cattle, 419,465 sheep, and 988,566 swine. There were in addition 28,460 horses and 111,764 cattle not on farms.—The number of manufacturing establishments was 3,836, having 406 steam engines of 10,826 horse power and 1,739 water wheels of 27,417 horse power, employing 17,871 hands, of whom 15,078 were males above 16, 1,498 females above 15, and 1,295 youth; capital invested, \$13,930,125; wages paid, \$4,844,508; value of materials, \$18,583,731; of products, \$31,196,115. The principal branches are shown in the following table:

INDUSTRIES.	No. of establishments.	Capital.	Value of products.
General implements and tools	19	\$40,550	\$77,450
Ships and boats	244	118,668	438,588
Wagons and carriages	41	182,500	432,100
Wagons and carriages	178	267,295	664,512
Wagons and carriages	8	122,150	205,900
Wagons and carriages	8	51,000	100,000
Wagons and carriages	25	2,064,000	2,332,647
Wagons and carriages	9	560,215	315,230
Wagons and carriages	8	51,500	100,000
Wagons and carriages	1,007	2,100,919	11,302,020
Wagons and carriages	17	60,900	214,208
Wagons and carriages	8	215,000	655,506
Wagons and carriages	4	12,300	47,312
Wagons and carriages	28	179,500	442,397
Wagons and carriages	100	118,800	254,900
Wagons and carriages	66	72,924	29,344
Wagons and carriages	7	80,000	571,200
Wagons and carriages	282	1,714,472	4,044,875
Wagons and carriages	42	805,700	1,004,822
Wagons and carriages	8	122,200	100,700
Wagons and carriages	8	170,000	164,000
Wagons and carriages	45	416,799	929,161
Wagons and carriages	61	92,189	178,000
Wagons and carriages	14	104,070	164,800
Wagons and carriages	4	82,000	56,970
Wagons and carriages	50	78,000	312,919
Wagons and carriages	20	110,000	472,674
Wagons and carriages	25	42,150	118,940
Wagons and carriages	11	604,453	802,500

are three ports of entry, Savannah, Brunswick, and St. Mary's. The imports from reports to foreign countries, with the ship-belonging to the several ports, for the ending June 30, 1878, are shown in the following table:

PORTS.	Value of imports.	Value of exports.	VESSELS REGISTERED, ENROLLED, AND LICENSED.	
			No.	Tonn.
Ships	\$-20,230	\$82,675,500	79	15,867
Boats	4,000	97,107	16	2,211
Yachts	795	172,007	5	886
Total	\$-25,140	\$82,844,614	100	21,190

Exports consist almost wholly of cotton lumber, the cotton being shipped from Savannah. The quantity of the former was 376,457 bales, valued at \$32,169,060; of the latter, 1,000 feet of boards, clapboards, deals, and 3,176,457 cubic feet of timber, total valued at \$1,609,140. Of the vessels, 9,009 tons were steamers. The entrances clearances were as follows:

PORTS.	ENTERED.				COASTWISE.

—The mileage of railroads in the state at different periods has been as follows: in 1841, 271; in 1851, 795; in 1861, 1,490; in 1871, 2,108. The Central railroad of Georgia, which extends from Savannah to Macon, leases and operates the Augusta and Savannah railroad, from Millen to Augusta; the Milledgeville and Eatonton, from Gordon to Eatonton; the Southwestern, which extends from Macon to Eufaula, Ala., 144 m., with branches from Fort Valley to Columbus (72 m.), Smithville to Albany (28½ m.), Cuthbert to Fort Gaines (30 m.), Fort Valley to Perry (18 m.), and Albany to Arlington (36 m.); the Macon and Western, from Macon to Atlanta; and the Upson County railroad, from Barnesville to Thomaston. The Georgia railroad, from Augusta to Atlanta, with branches from Camak to Warrenton (4 m.), Union Point to Athens (40 m.), and Barnett to Washington (18 m.), operates the Macon and Augusta line, which connects Warrenton and Macon. The Western and Atlanta railroad, from Atlanta to Chattanooga, Tenn., 128 m., was built by the state. The other lines are the Alabama and Chattanooga, from Chattanooga, Tenn., to Meridian, Miss., 295 m.; the Atlanta and West Point, between those places; the Atlantic and Gulf, from Savannah to Beaufort, with branches from Thomasville to Albany (58½ m.), and from Lawton to Live Oak, Fla., 48½ m.; the Brunswick and Albany, between those points; the Cherokee, from Cartersville on the Western and Atlantic to Rockmart, to be extended to Pryor, Ala., 29 m. further; the Macon and Brunswick, between those places, with a branch from Cochran to Hawkinsville (10 m.); the North and South (in progress), from Columbus to Rome, 135 m.; the Rome, from that point to Kingston; the Savannah and Charleston, between those cities, 104 m.; the Savannah, Griffin, and North Alabama (operated by the Macon and Western), from Griffin to Newnan, to be extended to Guntersville, Ala., 116 m. further; the Selma, Rome, and Dalton, from Selma, Ala., to Dalton, 236 m.; the Atlanta and Richmond Air Line, from Atlanta to Charlotte, N. C., 263 m.; and a branch of the East Tennessee, Virginia, and Georgia railroad, from Cleveland, Tenn., to Dalton, 27 m. The mileage of these roads and branches in operation in Georgia in 1872, with the capital stock and cost as far as reported of those lying wholly or chiefly in the state, is shown in the following table:

RAILROADS.	Mile- age.	Cost of road and equipments.	Capital stock.

The canals of this state have been constructed for local convenience: that around the falls of the Savannah, at Augusta, is 9 m. long; another (16 m.) connects the Savannah and Ogeechee rivers, and another (12 m.) connects Brunswick and the Altamaha, making a total length of 37 m. All the chief towns are connected by telegraph. The number of national banks in 1873 was 12, having an aggregate capital of \$2,725,000; of state banks (including 3 savings banks and 2 trust companies), 16, with \$4,082,000 capital. There were 7 insurance companies in 1872, of which 2 were life companies, having a capital of \$1,785,418. —The government is administered under the constitution of 1868, which ordains that there shall be neither slavery nor involuntary servitude except as a punishment for crime, that the social status of the citizen shall never be the subject of legislation, that there shall be no imprisonment for debt, and declares that every citizen owes paramount allegiance to the constitution and government of the United States, and that the state shall ever remain a member of the American Union. All elections are by ballot, and the right of suffrage is conferred upon every male person 21 years old and upward who is a citizen of the United States, or has legally declared his intention to become such (except idiots, insane persons, and those who have been convicted of heinous crimes), who shall have resided in the state six months before the election, and 30 days in the county in which he offers to vote, "and shall have paid all taxes which may have been required of him, and which he may have had an opportunity of paying, agreeably to law, for the year next preceding the election." No one convicted of felony or larceny, unless pardoned, nor any defaulter in public funds, is eligible to office; nor can any resident of the state who sends or ac-

cepts a challenge, or engages in or aids in a duel, vote or hold office. General elections commence on the Tuesday after the first day of November, unless otherwise provided by law. The legislative power is vested in a general assembly, consisting of a senate and a house of representatives. For senatorial purposes the state is divided into 44 districts, each electing one senator. The senators are elected for four years, one half retiring biennially. They must be citizens of the United States, 30 years of age, and have resided two years in the state and one year in the district from which they are elected. The house of representatives consists of 175 members apportioned among the counties, who are elected for two years and must be citizens of the United States, 21 years of age, and have resided one year in the state and six months in the county from which they are elected. The legislature convenes annually on the second Wednesday in January, and no session can continue more than 60 days unless prolonged by a vote of two-thirds of each house. Appropriations to "any corporation or associations" are prohibited. No town or city can be granted permission to become a stockholder in or to control any railroad or work of public improvement unless a majority of the voters of the state have placed restrictions upon the power of the state to become a stockholder in or to control its credit to any company. The executive power is vested in a governor, elected by a majority vote of the people, who holds office for four years or until his successor is qualified. If no candidate receives a majority, the general assembly chooses one of the candidates who have the highest number of votes. The governor must be 30 years of age, for 14 years a citizen of the United States, and for five years a resident of the state. He is the commander-in-chief of the army and navy of the state and the militia, may grant reprieves and pardons except in cases of impeachment, and may veto upon acts of the legislature which he may not overcome by a two-thirds vote of each house. In case of the death, resignation, or removal of the governor, the president of the senate and in case of the latter's inability, the speaker of the house of representatives, or the governor until the disability is removed, his successor is elected. There are a secretary of state, comptroller general, treasurer, surveyor general, elected by the people, and by the assembly, an attorney general, a school commissioner, elected by the people, or with the consent of the assembly, who hold office for four years. Impeachment is vested in the house of representatives. The senate, presided over by the judges of the supreme court, tries the case of the court for the trial of impeachments. No person can be convicted unless by a concurrence of two-thirds of the members present. The supreme court consists of five judges, who hold office for 12 years.

ring every four years, and has appellate jurisdiction only of cases from the superior courts and the city courts of Savannah and Augusta. There is a judge of the superior court for each of the 19 judicial circuits, who holds office for eight years. These courts, except in matters of probate, have general original jurisdiction both civil and criminal, at law and in equity, issue writs of *certiorari* to inferior tribunals, and may have appellate jurisdiction conferred upon them by law. A session is held twice a year in each county. The judges are appointed by the governor with the consent of the senate, and may be removed by him upon the address of two thirds of each branch of the legislature, or upon impeachment and conviction. The judges of the supreme and superior courts and the attorney general must be 30 years of age, for three years citizens of the state, and must have practised law seven years. There is an ordinary for each county, elected by the people thereof for four years, who holds a court of ordinary and probate; from his decisions there may be an appeal to the superior court. A justice of the peace is elected by the qualified voters of each militia district for four years. Justices have jurisdiction in civil cases in which the sum claimed does not exceed \$100; when the amount is more than \$50, an appeal may be taken to the superior court. A notary public (*ex officio* a justice of the peace) for each militia district may be appointed by the governor for four years. County courts presided over by a single judge in each county were established by the act of Jan. 19, 1872, in most of the counties. The judges, who have the same jurisdiction as justices of the peace, are appointed by the governor with the consent of the senate for four years, and must be 25 years of age and residents of the county for which they are appointed. Each head of a family is entitled to exemption from execution on a homestead of realty to the value of \$2,000 in specie, and personal property to the value of \$1,000 in specie, "except for taxes, money borrowed and expended in the improvement of the homestead, or for the purchase money of the same, and for labor done thereon or material furnished therefor, or removal of encumbrances thereon." The militia consists of all able-bodied males 18 to 45 years of age, except those conscientiously opposed to bearing arms, who may purchase exemption. Amendments to the constitution may be proposed by a two-thirds vote of each house of two successive legislatures, after which they must be ratified by the people. No convention of the people shall be called by the legislature in the election of delegates to which any person qualified to vote by this constitution is disqualified, nor unless the representatives therein shall be based on population. Georgia is entitled to nine representatives in the lower house of congress. The rate of interest is 7 per cent. All property owned by a married

woman at the time of marriage, and all that may be given to and inherited or acquired by her, is her separate property, and not liable for the debts of her husband. A married woman may sue and be sued in matters pertaining to her separate estate as though single, and with the consent of her husband may trade as a *feme sole*. No total divorce can be granted except on the concurrent verdict of two juries. The grounds of total divorce are intermarriage within the prohibited degrees, mental or physical incapacity at the time of marriage, adultery, wilful and continued desertion for three years, conviction of crime and sentence to the penitentiary for two years or more, force, menace, duress, or fraud in procuring the marriage, and pregnancy at the time of marriage unknown to the husband. For cruel treatment or habitual drunkenness the jury may grant either a partial or a total divorce. Treason in the first degree, murder, arson of an occupied dwelling or of a house in a city, town, or village, castration, and rape may be punished with death. Other punishments are fines, imprisonment, and whipping, not more than 39 lashes.—According to the federal censuses, the valuation of property has been as follows:

YEARS.	ASSESSED VALUE.			True value of real and personal.
	Real.	Personal.	Both.	
1850 ..				\$335,425,714
1860 ..	\$179,501,441	\$494,490,946	\$614,282,857	645,951,237
1870 ..	148,945,216	88,271,808	227,219,519	268,130,207

The diminution in the value of personal property is chiefly owing to the emancipation of the slaves. In 1870 the taxation not national amounted to \$2,627,029, of which \$945,394 was state tax, \$906,270 county tax, and \$775,365 town, city, &c., tax. The public debt was \$21,753,712, of which \$6,544,500 (funded, but not including bonds issued subsequently to 1868) was state debt; \$561,735, of which \$300,386 was funded, county debt; and \$14,647,477 town, city, &c., debt, of which all but \$264,162 was funded. The total receipts into the state treasury during the fiscal year amounted to \$1,164,304, of which \$732,898 was from general taxes, \$35,924 from liquor tax, \$5,778 from licenses, \$21,446 from corporations, \$45,000 from state railroad, \$10,292 from interest, \$310,000 from loans, and \$2,966 from miscellaneous sources. The disbursements amounted to \$1,444,817, of which \$17,035 was for the executive department, \$526,891 for legislative expenses, \$35,280 for the judiciary, \$2,547 for penitentiary expenses, \$114,647 for institutions for deaf and dumb, blind, and insane, \$20,000 for educational purposes, \$57,321 for printing, \$495,608 for payments and interest on public debt, and \$175,488 for miscellaneous expenses. The treasurer in his report for the year ending Dec. 31, 1873, gives the outstanding debt of the state, Jan. 1, 1874, as follows:

BONDS.

WHEN ISSUED.	When due.	Amounts.
1844 and 1848.....	1874	\$237,000
1873 .....	1875	100,000
1873 .....	1876	100,000
1873 .....	1877	100,000
1858 and 1873 .....	1878	200,000
1859 and 1873 .....	1879	300,000
1860 and 1873 .....	1880	300,000
1861 and 1873 .....	1881	200,000
1873 .....	1882	100,000
1873 .....	1883	100,000
1873 .....	1884	100,000
1873 .....	1885	100,000
1866 and 1873 .....	1886	4,000,000
1870 .....	1890	2,098,000
1872 .....	1892	307,500
Total.....	....	\$8,842,500

The issue of 1870 is gold bonds; the rest, currency. The total annual interest is \$586,460. During the administration of Gov. Bullock, 1868-'71, bonds to the amount of \$8,360,000 were issued, and the state indorsed bonds of various railroad companies to the amount of \$7,923,000. It having been charged that the greater part had been illegally and fraudulently issued or indorsed, a committee was appointed by an act of Dec. 9, 1871, to investigate the subject, which sat at Atlanta during March and April, 1872. Of the state bonds \$2,280,000 were returned and cancelled, \$3,482,000 were declared null and void by the legislature in accordance with the report of the committee, and \$2,598,000 were recognized as valid, \$2,098,000 of this amount being included in the preceding table. Of the indorsed bonds \$240,000 were returned and cancelled, with respect to \$4,475,000 all obligation is disclaimed, while \$194,000 of the Alabama and Chattanooga railroad, \$464,000 of the South Georgia and Florida railroad, and \$2,550,000 of the Macon and Brunswick railroad, in all \$3,208,000, are admitted to be binding upon the state. This amount being added to the aggregate of the table, the total recognized debt at the beginning of 1874 becomes \$11,550,500. The receipts during 1872, with the balance on hand at the beginning of the year, are shown in the following table:

Cash on hand, Jan. 1, 1872 .....	\$150,767 01
Received from general tax.....	946,514 75
"    from rent of Western and Atlantic railroad.....	300,000 00
"    from sale of bonds.....	188,379 63
"    from poll tax.....	128,972 48
"    from school tax.....	108,706 20
"    from sale of United States land scrip..	90,202 17
"    from temporary loans.....	47,752 50
"    from tax on insurance companies.....	25,711 93
"    from railroad, bank, and express tax..	21,482 14
"    from restitution money.....	19,674 21
"    from pay for convict labor.....	9,577 26
"    from liquor tax.....	9,333 30
"    from balance from Fourth Nat'l bank	7,538 48
"    from tax on circuses.....	8,201 25
"    from dividends on Georgia railroad stock.....	3,031 50
"    from special reciprocity tax on insurance .....	2,593 83
"    from rent of capitol.....	1,966 83
"    from miscellaneous sources .....	4,401 10
Total.....	\$2,101,840 84

The disbursements were \$1,335,207 14. \$692,892 paid on public debt, \$295,327 special appropriation, \$172,251 92 on legislative pay rolls, \$99,403 49 on civil ment, \$39,628 72 on contingent fund, \$23 on printing fund, \$5,261 32 on fund, and \$3,564 73 on overpayment on cash on hand Jan. 1, 1873. \$776,183 which \$100,000 was set apart to pay maturing on that day, and \$108,706 20 longed to the special and \$184,271 to general school fund. The total receipts 1873 were \$2,406,655 04; total disbursements \$2,250,232 49. The state owns and Atlantic railroad, valued at \$10,000 shares of stock in the Atlantic Gulf railroad company (par value \$200,000; and 186 shares in the railroad and banking company. \$18,600 \$7,218,600. It also owns 1,833 bank of the State of Georgia and in the bank of Augusta, but they have no net value. The Western and Atlantic was leased to a company for 20 years, cember, 1870, at the monthly rent of \$248,620,466, of which \$226,633, is available. The taxable property in 1873 to \$242,487,882. The rate of tax 40 cents per \$100; 40 cents for general and 10 cents for school purposes. The academy for the deaf and dumb, at Cave Spring, Floyd co., in 1873 had 5 instructors, 29 pupils, of whom 29 were males and 21 females. The academy for the blind, at Milledgeville, had 2 instructors (2 blind) and 47 pupils. Lunatic asylum, near Milledgeville, had 2 non-resident; number 61, Jan. 1, 1873, 576. The penitentiary is at Milledgeville. The convicts, 664 in number and 571 colored), are all leased to the state, and employed on public works in different parts of the state. The state has one officer, the principal keeper, and derives a revenue from the labor of the convicts. Since the civil war no common schools have been established in the state, although certain funds have been set apart, and were used in various counties, for the education of children. The constitution gave to the legislature to establish a system of common schools, and to carry them into effect an act was passed in 1868, which has since been superseded by the act of Aug. 23, 1872. The board of education, consisting of the governor, attorney general, comptroller general, and the state commissioner, is an advisory body to the constitution, and hears as a court of last resort on his decisions touching the construction of the school laws. The commissioner is charged with the execution of the school laws, and the intendent of the public schools, and the school revenue to the state.

portion to the number of youth from 6 to 30 years of age and of confederate soldiers : 30 years of age resident in each, and required to make an annual report to the state. Each county constitutes a school district, under the control of a county board of education consisting of five freeholders, who are elected for four years by the grand jury. The board chooses a secretary for the same who is *ex officio* the county school commissioner, divides the county into subdistricts, and in each is required to establish one or more primary schools, and, where the parents demand them, graded schools from primary to the high school grade. The county boards have a general supervision of the schools and school houses of their counties, paying the teachers, and prescribing the books, but no sectarian nor sectional books can be used, nor can the Bible be excluded from the public schools. These boards constitute a tribunal for the determination of any controversy respecting the construction and administration of the school laws, and are applying from their decisions to the state school commissioner, and are required to provide separate schools, with equal facilities, for white and colored children. The county school commissioner is the medium of communication between the state commissioner and the subordinate school officers; he is required to visit each school in his county at least twice a year, to make an annual census of the children of school age, to apportion the school fund of the county to the subdistricts in proportion to the number of such children in each, and to make annual reports to the state commissioner as may be required. He examines teachers, who are licensed by the county board, and are divided into three grades, with licenses continuing one, two, and three years respectively. No county is entitled to its share of the state school fund unless the county board has provided by tax or otherwise for keeping primary schools in operation for three months in the year, or for three months in the case of ambulatory schools, which may be established in counties in which the sparseness of population it is impracticable to maintain schools for three months. The schools are free to the children of the respective school districts. The county boards may establish evening schools for youths over 12 years of age who cannot attend during the day, and under the direction of the state board may organize self-sustaining manual labor schools. Public school buildings and furniture on the site (not more than four acres) of a public school house are exempt from taxation and from seizure on execution. The school system of two counties and of four counties is organized under special laws. The school fund consists of the proceeds of the poll tax and of the taxes on spirits and exhibitions, and on the sale of spirituous and malt liquors, one half of the monthly rents made by the lessees of the Western and Atlantic railroad, the dividends on 186

shares of the Georgia railroad and banking company, set apart as a permanent educational fund by the act of Jan. 22, 1852, and the interest (6 per cent.) on \$350,000 in bonds issued under the act of Dec. 11, 1858, as a permanent school fund. By an act of 1818 certain lands or the proceeds thereof were set apart for the education of poor children, but it is believed that but a small portion is now available. By the act of Feb. 19, 1873, it is provided that when legal bonds of the state are purchased and cancelled, or paid off, the same amount of bonds having 100 years to run shall be issued by the governor payable to the school fund, and that the interest on these at the rate of 7 per cent. per annum shall be paid semi-annually for the support of the public schools. From the adoption of the constitution of 1868 to Dec. 1, 1873, \$739,722 42 belonging to the school fund had been collected, of which \$354,418 89 had been diverted to other uses, but measures had recently been taken to restore it to the proper channel. The present school revenue is about \$250,000 a year. The state school commissioner in 1873 reported (two counties wanting) 849,164 children of school age, of whom 198,816 were white and 150,848 colored. Public schools were in operation in 120 counties; 89 reported 1,379 white and 356 colored schools; number of pupils enrolled, 76,157, of whom 58,499 were white and 17,658 colored; average attendance, 82,224. According to the United States census of 1870, the state contained 1,880 schools, having 2,482 teachers (1,517 male and 915 female), 66,150 pupils (32,775 male and 33,875 female), and an annual income of \$1,258,299, of which \$66,560 was derived from endowments, \$114,626 from taxation and public funds, and \$1,072,113 from other sources, including tuition fees. Of this number 246 were public schools, viz.: 4 normal, 9 high, 26 grammar, 18 graded common, and 189 ungraded common, having 327 teachers, 11,150 pupils, and an income of \$175,844, of which \$59,293 was derived from taxation. Of the schools not public, 151 were classical (28 colleges and 123 academies), 8 professional (1 law and 7 medical), and 9 technical (3 commercial, 1 for the blind, 1 for the deaf and dumb, and 4 of art and music). Of the residue, 1,452 were day and boarding schools and 19 parochial and charity schools. The colleges had 77 male and 56 female teachers, 978 male and 1,620 female pupils, and an income from endowments of \$36,850, and from other sources of \$112,516. The university of Georgia, at Athens, was chartered in 1795 and organized in 1801. It has a permanent endowment of \$100,000, derived from the sale of lands set apart in 1784 by the revolutionary statesmen and soldiers of Georgia, to found a university. The interest on this sum, which has been invested by the legislature, is paid by the state. The university has a preparatory department, an academic department, embracing the ordinary branches of collegiate study, and a law department. The state college of

agriculture and the mechanic arts, endowed with the congressional land grant of 270,000 acres, which has been sold for \$243,000, was organized as a fourth department in 1872; it embraces instruction in agriculture, engineering, and chemistry. Students intending to enter the Christian ministry are relieved from payment of tuition when in need of aid, and other poor students, residents of the state, to the number of 50 annually, have their tuition remitted, in return for which they are expected to teach in some school in Georgia as many years as they have resided at the university. The number of professors and instructors in 1872 was 15, including 2 in the law and 3 in the preparatory department; number of students, 317, viz.: 7 resident graduates, 255 undergraduates (including 15 law students), and 55 in the preparatory department; number of volumes in the college and society libraries, 20,000. The North Georgia agricultural college, at Dahlonega, became toward the close of that year a branch of the state college and a department of the university. Atlanta university, in the city of that name, was established in 1867 by the freedmen's bureau and the American missionary association. It is not restricted as to color or sex, but is designed especially for the higher education of colored youth. Preparatory, normal, collegiate, agricultural, and theological departments have been organized, and in 1872 there were 7 instructors and 178 students. Oglethorpe university (Presbyterian), also at Atlanta, had 5 professors, 48 collegiate and 62 preparatory students; but it has since been suspended for want of funds. Mercer university (Baptist), at Macon, in 1871 had 5 professors and instructors, 82 students, and a library of 5,000 volumes. It has a theological department. Emory college (Methodist Episcopal church south), at Oxford, in 1872 had 12 professors and instructors, 50 preparatory and 189 collegiate students, and a library of 3,000 volumes. Bowdon college, at Bowdon, Carroll co., had 4 professors and instructors and 22 students. The other institutions classed as colleges are chiefly for the superior instruction of females. The principal are Furlow Masonic female college at Americus, Griffin female college at Griffin, Hamilton female college at Hamilton, the Southern female college at La Grange, the Wesleyan female college at Macon, the Georgia female college at Madison, Marietta female college at Marietta, La Vert female college at Talbotton, West Point female college at West Point, and Monroe female college at Forsyth. The Atlanta medical college in 1872 had 14 professors and instructors and 52 students. The medical college of Georgia, at Augusta, had 10 professors and instructors, 103 students, and a library of 5,000 volumes. The Savannah medical college in 1872 had 14 professors and instructors, 36 students, and a library of 3,000 volumes. The census of 1870 returns 1,735 libraries, containing 467,232 vol-

umes, of which 545, having 162,851 volumes were not private, classified as follows: 1, with 16,000 volumes; town, city, &c., with 3,730; court and law, 63, with a school, college, &c., 15, with 41,100; school, 369, with 63,114; church, 62, with 16,002; historical, literary, and scientific societies, 2, with 2,000; benevolent and secret societies, 1, with 400; circulating, 8, with 11,895. Besides the college libraries the principal are those of the young men's library association at Atlanta (3,000 volumes), of mechanics' and scientific association at Columbus (8,000), and of the Georgia book society at Savannah (7,000). There are 15 newspapers and periodicals, issuing 15,000,000 copies annually, and having an average circulation of 150,987, viz.: 15 daily, circulate 30,800; 5 tri-weekly, 3,600; 9 semi-weekly, 5,100; 73 weekly, 88,837; 2 semi-monthly, 700; and 6 monthly, 21,950. They were classified as follows: agricultural and horticultural, 6; illustrated, literary, and miscellaneous, 6; political, 93; religious, 4; technical and professional, 2. The number of church organizations was 2,873. The number of edifications, and the value of church property, is shown in the following table:

DENOMINATIONS.	Edifices.	Value.	Prop.
Baptist .....	1,812	850.	
Christian .....	28	10,000	
Congregational .....	10	2,000	
Episcopal .....	27	10,000

Methodist .....	1,154	327,248	
Presbyterian .....	128	40,573	
Roman Catholic .....	11	3,500	
Universalist .....	8	700	
Union .....	6	1,100	
Total .....	2,005	501,145	

Of the thirteen provinces which claimed themselves independent in 1776, Georgia was the latest settled. The country between its present boundaries was a wilderness from 1733, and, though comparatively settled by the charter of Carolina, had remained in the hands of Spain as well as England. On June 9, 1732, George II., in his proclamation received its name, granted the charter of incorporation entitled the "Trustees for the Colony of Georgia." The colony was proposed in the year 1732, and was established on the one hand, to provide a refuge for the destitute at home, and on the other, to protect the frontiers of the Carolina colonies from the incursions of the Indians and Spaniards. In November of 1732, 33 persons were embarked at London, under the direction of Gen. James Oglethorpe, who arrived at Charleston in January, 1733, and this place Oglethorpe explored, and soon after purchased land from the Creeks. On a river the foundation was laid for the city of Savannah.

which received the name of Savannah. Here the settlement was commenced in the spring of 1733. The condition upon which the lands were parcelled out was military duty, and so grievous were the restrictions to which the colonists had to submit that many returned into Carolina, where the lands were held in fee simple. The number of inhabitants in the colony nevertheless continued to increase, considerable accessions to its population being received from Germany and Scotland. In 1739 war broke out between Spain and England, and Gen. Oglethorpe was appointed to the command of the South Carolina and Georgia troops. Having mustered 1,000 men and a number of Indian allies, he invaded Florida, but, failing in an expedition against St. Augustine, returned unsuccessful. In 1742 this invasion was retaliated, and a Spanish fleet of 36 ships and 5,000 men appeared in the Altamaha river, took Fort St. Simon, and were proceeding against Fort Frederica, on St. Simon's island, when from a stratagem conceived by Oglethorpe they became alarmed, retired to their ships, and sailed for Florida. Peace was soon restored; but restrictions of various kinds, and especially the prohibition of slavery, rendered the people discontented, and many abandoned their settlements, while those who remained with difficulty obtained a scanty subsistence. The restrictions upon slavery were removed about 1750, and in 1752, the trustees having surrendered their charter to the crown, Georgia became a royal government, with privileges and regulations similar to those of the other colonies. The first good effect of the change of government was felt in the establishment of a general assembly in 1755. The limits of the colony to this time were the Savannah on the north and the Altamaha on the south, extending westward to the Pacific. In 1763 all the lands between the Altamaha and St. Mary's were annexed to Georgia by a royal proclamation. From this period the colony made rapid progress; the rich swamps and lowlands on the rivers were brought into cultivation, and production rapidly increased. At the commencement of the revolution the colonists did not hesitate to make the grievances of their northern brethren their own, and take part in the coming struggle. In July, 1775, a convention gave the sanction of the colony to the measures of congress, and appointed delegates to that body. During the war that ensued Georgia was overrun by British troops, and the principal inhabitants were compelled to abandon their homes and fly into the neighboring states. In 1778 Savannah was captured, and in 1779 Augusta and Sunbury. In the latter year an unsuccessful attempt was made by the Americans and French to recapture Savannah. Georgia framed its first constitution in 1777, a second in 1789, and a third in 1795, which was several times amended. The constitution of the United States was ratified by Georgia on Jan. 2, 1788. After

the revolutionary war Georgia suffered on her frontiers from the incursions of the Creeks and Cherokees. In 1790 and 1791 treaties were concluded with the chiefs of those nations. By the treaty of Fort Wilkinson in 1802 the Creeks ceded to the United States a large tract which has since been assigned to Georgia, and now forms the S. W. counties of the state. In the same year Georgia ceded to the United States all its claims to the lands westward of its present limits. Subsequently serious difficulty arose between the state and national governments respecting the Cherokees, which was terminated by the removal of that tribe in 1838 to the Indian territory, when Georgia came into possession of their lands. In the presidential election of 1860 the vote of Georgia was 51,889 for Breckenridge, 42,886 for Bell, and 11,590 for Douglas. Immediately after the result became known the legislature (Nov. 18) ordered an election to be held on Jan. 4, 1861, for the choice of delegates to a convention to consider the question of withdrawing from the Union. This convention, consisting of 301 delegates, assembled at Milledgeville on Jan. 16, and on the 19th passed an ordinance of secession by a vote of 208 to 89. A proposition to call a congress of the disaffected states, with a view to coöperation, was defeated by a vote of 164 to 133. All the delegates subsequently signed the ordinance except six, who caused an entry to be made in the journal that they acquiesced in the will of the majority. On the 24th 10 delegates were appointed to the congress of the seceded states, to be held at Montgomery, Ala., Feb. 4, and on March 16 the constitution of the Confederate States was unanimously ratified. Ordinances were also passed resuming jurisdiction over places ceded to the United States, and transferring all forts, arsenals, and munitions of war to the confederate government. On Jan. 3, 1861, Fort Pulaski, on Cockspur island at the mouth of the Savannah river, mounting 60 guns, was seized by order of Gov. Brown, and at the same time Fort Jackson, 4 m. below Savannah, was occupied. On the 24th the arsenal at Augusta, containing two 12-pound howitzers, two cannon, about 20,000 small arms, and large stores of ammunition, was taken possession of by 700 state troops under Gov. Brown. Georgia, except on the coast, was not the theatre of active hostilities until 1864. On Nov. 25, 1861, Com. Du Pont, who had just taken Port Royal, S. C., occupied Big Tybee island at the mouth of the Savannah, and soon after other points commanding Fort Pulaski were taken possession of, and that fort was reduced, April 11, 1862, by a bombardment from batteries erected on Tybee island. Early in March Com. Du Pont, with a fleet from Port Royal, took possession of St. Mary's, Brunswick, Darien, and St. Simon's island, and left a small force at each. On Feb. 28, 1863, the Nashville, a confederate ironclad, was destroyed in the Ogeechee river by Commander Worden; and on March 3 an

ineffectual attack was made on Fort McAllister on the same river, a few miles S. W. of Savannah, by a federal fleet. On June 11 Darien was burnt, and on June 17 Capt. John Rodgers in the Woehawken disabled and captured in Warsaw sound the confederate ironclad Atlanta, which had just come down from Savannah. A portion of the operations around Chattanooga in the autumn of 1863 took place in N. W. Georgia. On May 6, 1864, commenced the decisive campaign from Chattanooga under Gen. Sherman, which resulted, after a persistent resistance and much severe fighting, in the evacuation of Atlanta by the confederates on Sept. 1. Sherman started, Nov. 11, on his memorable march to the sea. Passing through the heart of Georgia, he entered Milledgeville on the 23d, and reached the vicinity of Savannah on Dec. 10. On the 13th Fort McAllister was taken by storm, and on the 21st Savannah was occupied, having been evacuated the night before by the confederates under Gen. Hardee, who had destroyed the navy yard, two ironclads, several smaller vessels, and much ammunition and stores. A cavalry force under Gen. Wilson in April, 1865, entered Georgia from Alabama, took Columbus and West Point, arrived at Macon on the 21st, and captured Jefferson Davis, the fugitive president of the confederacy, at Irvinville, May 10. Andersonville in this state was the seat of the most noted of the confederate military prisons, and there was another at Millen, which was removed upon the approach of Gen. Sherman. After the surrender of the confederate armies, the state was under the control of the military until June 17, 1865, when President Johnson appointed James Johnson, a citizen of the state, provisional governor, with power to call a convention of delegates chosen by the citizens loyal to the United States, who were qualified as voters by the laws in force immediately before the passage of the ordinance of secession, and who should take the oath prescribed in the amnesty proclamation of May 29. The election of delegates took place Oct. 4, and the convention, assembling at Milledgeville on the 25th, remained in session 13 days, during which time it repealed the ordinance of secession and acts in pursuance thereof, declared the war debt void, amended the constitution by abolishing slavery and in other respects, and ordered an election to be held on Nov. 15 for governor, members of the legislature, and congressmen. The legislature convened Dec. 4, and soon afterward ratified the amendment to the constitution of the United States abolishing slavery, by a unanimous vote. On the 14th Charles J. Jenkins, who had been elected governor, was inaugurated, and on the 19th the provisional governor was instructed to turn over to him the government of the state. These measures not meeting with the approval of congress, the senators and representatives were not admitted to seats; and under the reconstruction acts of 1867 Georgia, with Alabama

and Florida, was constituted the third division, and placed in command of Pope. A registration of those entitled under these acts was subsequently made. 192,285 voters were registered, white and 95,973 colored. An election held during the five days commencing April 20 and the three following days, which resulted in a large majority for the constitutional convention (the whites generally refraining from voting), and in the choice of delegates, of whom 33 were colored. A convention met at Atlanta Dec. 9, and after a long session, adjourned finally March 11, 1868, after adopting a constitution, and providing for an election on its ratification or rejection and for the election of state officers and congressmen, which was held April 20 and the three following days. The result was a majority of 17,699 for ratification and the election of Rufus B. Bullock, republican, by 7,047 majority over John B. Gordon, democrat. The legislature composed of 73 republicans and 102 democrats in the house, and 8 senators and 25 representatives were elected. On June 25 an act of congress was passed providing for the readmission of Georgia and other states, upon the ratification of the 14th amendment to the constitution of the United States, and the repeal of certain provisions of the constitution prohibiting suits on debts contracted before June 1, 1865. The legislature of Georgia complied with the conditions by a vote of 24 to 14 in the senate and 89 to 70 in the house, and on the following day Gov. Bullock was sworn in as governor of the United States. On the 29th the state was turned over to the civil government. The congressional representatives were admitted to seats on the 30th, but the members of the legislature were still excluded. In the election of the candidates having the largest number of votes in the respective counties were admitted to their places, and the laws of the state were continued, which was one of its provisions, and the government office. This action was approved by the executive at Washington as a violation of the reconstruction acts and of the conditions upon which the state had been admitted to the Union. The organization of the 41st congress was completed, and representatives from Georgia were admitted to take their seats in the supreme court of the United States. The congress passed an act providing for the readmission of persons declared by the executive to be rebels, who had succeeded Gen. Lee, and provided for the organization, and to ratify

to the constitution of the United States, title the state to representation in congress. By an order of Dec. 24 Major Gen. Terry was placed in command of the troops to carry the act into effect. The legislature met, Jan. 10, 1870, in pursuance of a proclamation by Gov. Bullock, and adjourned from time to time until the 26th of that month, when a session appointed by Gen. Terry to determine the eligibility of certain members reported at 21 as ineligible under the 14th amendment, or for refusing to take the test oath, and candidates having the next highest number of votes in the respective districts were seated in their places. Both houses were declared organized on the 31st, and on Feb. 2 the amendment was ratified by a vote of 28 to 10 in the senate and 55 to 29 in the house. Conditions prescribed in the reconstruction act of 1867 were also assented to, and subsequently United States senators were elected. On July 15 an act for the readmission of the state received the approval of the president. An election for congressmen was held Nov. 1, 1868, and they, together with the senators elected in 1868, having been admitted to congress in the following December, the reconstruction of the state became complete.

**GEORGIA** (Russ. *Grusia*; Pers. *Gurjistan*; *Iberia*), the name formerly applied to that part of western Asia comprised in the Russian Caucasus, lying between the Caspian and Black seas, and the Caucasian and Armenian mountains; area, about 70,000 sq. m. in its boundaries are included the Russian governments of Kutais, Tiflis, Elisabetopol, and Erivan, and the districts of Samtskhe, Sukhumi, and Tchernomore. These are the extreme limits of ancient Georgia, but in former times the name has generally been applied to the territory bounded N. by the Caucasus, E. by Shirvan, S. by the range of Armenian mountains separating the valley of the Kur from that of the Aras, and W. by a part of the Caucasian range, having an area of about 25,000 sq. m. The surface of the country is mountainous, but many of the rivers, especially that of the river Kur, which flows through it from W. to E., are of great fertility. The climate is agreeable and healthy, and the soil produces in abundance all the cereals, flax, hemp, flax, and cotton, and many fine fruits, particularly grapes, from which much wine is made. For a more particular description of the country see Russia and the articles on its modern governments and districts.—The Georgians, or ancient Iberians, including the kindred, the Suanethians, Mingrelians, Lazians, form the main race of the south-eastern division of the Caucasian group of the Mediterranean family of the human species. Their origin is believed to be derived from the Persians (*Gurj*) (*Gurjistan*, "the land of wolves"). They call themselves Kartveli or Kartlians, after the province Kartlia of the former Georgian empire. The Armenians call them Virk.

The Georgians proper occupy the country comprised within the more limited of the boundaries above given, and embracing Kartlia on the Kur, Kakhetia, N. E. of Kartlia, and other districts. West of them are the Mingrelians, who occupy Mingrelia, and Guria, on the Black sea. The Suanethians inhabit the southern slope of the Caucasus N. E. of the Mingrelians. These three divisions belong to the Russian empire. The Lazians in the sanjakate of Lazistan, pashalik of Trebizond, are subjects of Turkey. While the Armenians, who control most of the traffic of the country, are timid and intent on gain, the Georgians are bold, reckless, turbulent, and extravagant. They are also indolent, apathetic, and ignorant, seldom giving any signs of animation except when on a drinking bout. The lower classes are chiefly cultivators of the soil, which they work in the same way that their ancestors did centuries ago.

Georgian Costumes.

The Georgian men are noted for their athletic forms and the women for their beauty, although the features of the latter are regular and handsome rather than beautiful, and are wanting in expression. The general characteristics of the race are finely chiselled brows, large, black, liquid eyes, prominent semi-aquiline nose, and voluptuous mouth. Before marriage the women endeavor to keep their waists as small as possible by means of a girdle, which they wear almost continuously; this results in a large development of the bosom, which is much admired. It is said that in former times the belt was never removed until the nuptial day, when it was cut by the dagger of the bridegroom. Many such ancient customs, now obsolete in the neighborhood of Tiflis, are still preserved in the mountains and isolated districts. Before the Russian domination a large

trade in slaves was carried on with Turkey, the Georgian nobles deriving their chief revenue from the sale of their serfs, the men for the Turkish armies, the women for the harems; but the traffic is now interdicted, and the relations between the upper and lower classes are much modified. The Persians and Mussulmans from the north of India also purchased many women from this region for their harems, paying sometimes as high as 20,000 piastres for a remarkably beautiful one. The Georgian stock consequently is largely disseminated throughout Mohammedan countries. The Georgians are nominally members of the Greek church, and have had the Bible in their language since the beginning of the 10th century; but the priests are generally as ignorant as the people.—Nothing certain is known of early Georgian history. The statements of the Greek and Latin writers are confused and lead to various conclusions. George Rawlinson thinks that the territory was anciently "in the possession of a people called by Herodotus Saspeires or Sapeires, whom we may identify with the Iberians of later writers." The Colchians and Albanians were probably their neighbors. Their legends trace their origin to Targamos, a descendant of Japhet, and claim Mtkhetos as the founder of the ancient capital Mtkhta, which stood about 15 m. N. W. of Tiflis. The first Georgian empire seems to have been ended by the Scythians, who invaded it in the 7th century B. C. It is probable that it afterward formed a part of the Persian empire, was conquered by Alexander the Great, and regained its independence at his death. Pharnavas was the first or one of the first kings of the second Georgian empire. Mirvan, in the latter part of the 2d century B. C., and his son Pharnaj, sovereigns of Persian descent, introduced Parsecism, which led to a revolt. The king of Armenia came to the aid of the Georgians, and put his son Arsag on the throne, thus founding the dynasty of the Arsacides. In 65 B. C. the Georgians or Iberians came into contact with the Romans, and were compelled by Pompey to sue for peace. In the beginning of the 3d century A. D. the kingdom became highly prosperous, but in the following period the Persians made destructive invasions. Early in the 4th century the Georgians were converted to Christianity by St. Nina, a captive woman. At the death of Stephanos I. in 574, Guram, a Jew who had been his general-in-chief, ascended the throne. In 635 the Arabs overran the country, but did not succeed in subverting Christianity. Subsequent kings suffered much from their aggressions, and the Armenian dynasty of the Bagratides, who succeeded the Guramides, eventually became vassals of the caliphs. Bagrat III. liberated his country from foreign domination, and David III. (1089–1126) extended his dominions over a part of Armenia and as far as Trebizond. Queen Tamar III. (1184–1206) reduced several of the tribes north of

the Caucasus, and her son George IV. vanquished the Persians, converted many of them to Christianity, and rendered valuable aid to the crusaders. In the 13th century the Mongolians subdued the country, but in the middle of the 14th George VI. threw off the yoke and extended his sway over the neighboring provinces. Tamerlane reduced the country to subjection, but it was again liberated by George VII. In 1424 King Alexander divided his kingdom among his three sons, and the history of the next two centuries is one of conflicts between the three governments, and of quarrels with Persia and Turkey, in which Russia interfered. The country was reunited under Vakhtang IV. or V., whom the Persians call Shah Naos. He died in 1676, and for a century after Georgia was the scene of intestine feuds and divisions, in which the Turks and Persians took part. In 1783 Irakli (Heraclius) II. of Kakhetia, who had united under his sway a large part of the ancient kingdom, being pressed by the Persians, announced himself a vassal of Russia. His successors having new difficulties with the Persians and Lezgians, Georgia was made in 1801 a province of Russia, and in 1810 Imerethia was added to it.—The Georgian language is written in an alphabet of 40 letters, somewhat varying in different manuscripts. The following are used in Brosset's dictionary:

ს	A	ბ	B	გ	G	დ	D
ე	E	ვ	W	ზ	Z	ჲ	H
თ	TH	ი	I	ც	C	ლ	L
მ	M	ნ	N	ო	O	პ	P
ჟ	J	რ	R	ს	S		
ტ	T	უ	U	ფ	F	ქ	K
ყ	Q	ღ	GH	წ	CH		
ბ	TCH	ც	TZ	ძ	DZ	წ	TS
ჭ	DCH	ხ	KH	ჯ	KHH	წ	N
ჰ	H	ჲ	HO	ფ	F	წ	E

The characters used in the ecclesiastical style of writing differ from the common ones. The languages of the four tribes, the Georgians, the Mingrelians, the Suanethians, and the Lazians, are related to each other, and show a common development from one primitive form, either primitive Aryan or Dravidian; but there is no foundation for connecting them with the languages spoken by tribes north of the Caucasus. The Georgian is written from left to right. It makes no distinction of gender. To distinguish sex, the words male and female are introduced, except for the words king, queen, young man, young woman, him, and her. No article is used. There are two numbers, singular and plural, and six cases, nominative, genitive, dative, vocative, instrumental, and instrumental modal. There are special forms for the comparative and superlative of adjectives. Nouns are inflected by means of suffixes, and verbs by means of suffixes, prefixes, and changes in the radical letters. The verbs are either active, passive, reciprocal, or neuter, and are modified according to one of the 20 classes of conjuga-

tion into which they are divided. Prepositions govern either the genitive, dative, or instrumental.—Among the literary remains of ancient Georgia, some of the manuscripts written in the ecclesiastical style of alphabet are probably of high antiquity; but most of them date subsequently to the introduction of Christianity, and consist of homilies and translations of portions of Scriptures, and of Plato, Aristotle, and other Greek authors. Some manuscripts contain novels and romances; one gives in verse the history of Shah Naos, and several, dating principally from the 17th century, are poetical works of some merit. The most important of Georgian manuscripts are: a volume of 68 treatises, historical and biographical, which has thrown much light on the history of the Khazars during the 8th century; a translation of the Gospels by Droudeh, dating from the 10th century; and a romance entitled "Tariel, the Man with the Tiger Skin," a general of Queen Tamar, by Skhotta of Rustvel. The following is a facsimile of the last verse of Rustvel's romance:

ႁმირან ზარეჯანის-ბე ზოხეს თქიან ღონელსა.  
 ႁდუთღ- ზესიან ყაჯთელსა ჟუქსი მას თქეს რომელსა.  
 ზილარქელს სარგის ღმირგულსა, მას ებნ დანუბრო-  
 მელსა. და ღმირიელ მილსა ჟუტსოველსა. მის-თჳს  
 ცრემლ- მეთჳ ბრ-მელსა.

The literal translation is as follows: "Moses of Khoris has glorified Amiran, the son of Daredjan; the poem of Abdul Messia, written by Khevtel, and the history of Dilar by the indefatigable writer Geth Sargis of Tmogvi, were worthy of praise; but Rustvel has wept without ceasing over his Tariel." Among similar compositions, an epic on Queen Tamar, by Tchakhadze, ranks equally high. During the 18th century, in spite of the incessant wars that harassed the country, there was a rich supply of meritorious literature, and the language attained that definiteness, richness, and energy which are now its most prominent features. Prince Sul Khan-Saba-Orbelian published in that century a dictionary of the language, containing at least 25,000 words, and King Vakhtang VI. caused an extensive history of the country to be written. The Russian language has now generally superseded the Georgian in the schools, and books in the Georgian language are printed in Russian characters. The language and literature of the Georgians have been specially studied by Adeling, Brosset, Dorn, Josselin, Klaproth, Saint-Martin, and Tchubinoft. Brosset is considered the highest authority on the subject. Ethno-

logical studies of the Georgian race are contained in the books of travel of Cunyngname, Dorn, Dubois de Montpérenx, W. J. Hamilton, Haxthausen, Mounsey, Poulett-Cameron, and Wagner.—See *Histoire de la Géorgie depuis l'antiquité jusqu'au XIX<sup>e</sup> siècle, traduite du géorgien*, by Brosset (2 vols. 4to, St. Petersburg, 1849-'57); "History of Grusia," by Baratoff (St. Petersburg, 1865 *et seq.*); and *La Géorgie*, by De Villeneuve (Paris, 1871).

**GEORGIA GULF**, an arm of the sea lying between Vancouver island and the mainland of British Columbia, between lat. 48° 50' and 50° N., and lon. 122° 40' and 125° W. On the south it is connected with the strait of Juan de Fuca by Haro and Rosario straits, and on the north with Queen Charlotte sound. Howe sound and Jarvis and Burrard inlets run from it into the mainland. Fraser river flows into it. Its length is about 100 m.; greatest breadth, 80 m. At each extremity of the gulf is an archipelago, and it contains several large islands.

**GEORGIA BARK**, the common name of *Pinckneya pubens*, one of the handsomest of our native shrubs. It grows in bogs and along the banks of streams from South Carolina to Florida, and sometimes attains the height of 20 ft.,

though, as it throws up many stems from the same root, it retains a shrub-like form. It has the general botanical characters of the *rubiaceæ*, to which family it belongs. The leaves are large, oval, acute, and downy on the under surface, as are the flower clusters which are borne at the ends of the branches; these consist of several five-flowered fascicles of purplish-spotted flowers, with a tube nearly an inch long and a reflexed limb; the calyx is short and five-lobed, one of the lobes being expanded into a large, ovate, rose-colored leaf, which is more showy than the flower itself. The plant is closely related to *cinchona*, and is one of the many that have been proposed as substitutes for Peruvian bark. From the reports of physicians living in the states where it grows, it appears to have decided anti-periodic properties, though slower in its action than quinia. As an ornamental plant it is deserving of the attention of those who live in a climate where the winters are mild; in England it is sufficiently valued to be cultivated as a wall plant. The genus was named by Michaux in honor of Gen. Charles C. Pinckney.

**GEORGIAN BAY.** See **HURON, LAKE.**

**GEPIDE,** a Germanic people, akin to the Goths, who first appear in history in the 3d century A. C. as living on the Baltic near the Vistula. They subsequently moved further S. and settled N. of Pannonia, between the Ostrogoths on the east and the Visigoths on the west. They were at first compelled to follow Attila, but regaining their independence at his death, under their king Arderic, they drove back the Huns and occupied their territory on the lower banks of the Theiss, Danube, Drave, and Save. Theodoric, king of the Ostrogoths, defeated them in 488 near Sirmium (now Szerém in Slavonia), and Alboin, king of the Lombards, assisted by the Avars, destroyed their power in 566. The remnants of the people became gradually amalgamated with the conquerors.

**GERA,** a town in the German principality of Reuss-Schleiz, in a beautiful valley on the right bank of the White Elster, 35 m. S. S. W. of Leipsic; pop. in 1871, 17,959. It consists of the town proper and two suburbs, and is regularly built, having been restored in modern style after a great conflagration in 1780. It has manufactories of woollens, cotton, linen, camlet, porcelain, stoneware, tobacco, leather, soap, chocolate, glue, artificial flowers, musical instruments, and fire engines, iron founderies, large breweries and dyeing establishments, and carries on a considerable trade. Its old castle dates from 1086, when the place first became a town, and was bestowed on the baron of Reuss in the 12th century. Three railways connect the town with Zeitz, Gössnitz, and Eichicht.

**GERAMB, Ferdinand de,** baron, a French Trappist, born in Lyons, April 17, 1772, died in Rome, March 15, 1848. He was educated in Vienna, and served against the French in the Austrian, Spanish, and English armies. He was of a violent temper, and fought several duels. In 1812

he was in London, and his creditor to have him arrested, but he barricaded himself, hung out a flag inscribed "This is my castle," and resisted for a fortnight the sheriff and his deputies. He was sent to the continent, where he fell into the hands of Napoleon, by whose orders he was imprisoned in Vincennes and after La Force. In the latter prison he became a bishop of Troyes, and thenceforward dedicated his life to religion, joining the order some time after his release (1818). He took the vows in 1817 at the monastery of Port du Salut near Laval, and distinguished himself so greatly by his piety that he was appointed procurator general of the order in 1831. He made a pilgrimage to the Holy Land and in 1837 went to Rome. His *Pèlerinage à Jérusalem et au mont Sinai* (1833, 2 vols., Paris, 1836) has been translated into several languages, and passed, like his *La Trappe à Rome* (1838), and others, through many editions.

**GÉRANDO, Joseph Marie de,** baron, a philosopher and statesman, born in Lyons, Feb. 29, 1772, died in Paris, Nov. 1, 1854. He was educated in the college of the Holy Spirit at Lyons, and was preparing for the priesthood against the wishes of his family when the revolutionary persecutions of ecclesiastics changed his purpose. When in 1793 his native town was besieged by the troops of the convention, he took arms for its defence, but was made prisoner, and narrowly escaped. He entered the army, but his regiment being sent to Lyons, he was there recaptured and denounced, and obliged to seek safety elsewhere. He went to Switzerland and thence to France, where he was employed two years in a commercial office in Naples. In 1797 he returned to France, and joined a regiment of cavalry, and was afterwards garrisoned at Colmar when the institute proposed the question: "What is the influence of education on the formation of ideas?" De Gérando wrote a dissertation on it, and learned that he had received the prize soon after his return to Zürich, in which he had been employed. He then returned to Paris, where he entered the army as a volunteer under Lucien Bonaparte, and was afterwards secretary general of that department. He was in Champagne in 1804, accompanied by Napoleon, and in 1805, was appointed master of the ceremonies at the coronation of Napoleon. In 1808, he was afterwards engaged in the expedition to Tuscany and of the Papal States. When they were united to France, he was appointed councillor of state in 1811, and in 1812, pointed governor of Catalonia. At the fall of the empire he retired, but for having been a member of the defence of the Moselle during the invasion, he was at first discredited. He returned to France after the restoration, but soon became a member of the council of state, which he remained in the rest of his life. In 1819 he gave a series of lectures before the faculty of law on public and administrative law,

1822 and resumed in 1828. In 1825 he was raised to the peerage. His principal works are: *Des signes et de leur considération dans leurs rapports* (Paris, 1800); *De la génération humaine* (Berlin, 1802); *comparée des systèmes de philosophie* (Paris, 1803), of which a posthumous edition appeared in the third edition in 1825 he received the prize of the Académie for his treatise *Du perfectionnement de l'éducation de soi-même* (translated, Boston, 1830), the fundamental principle of which is that life is a discipline in perfection. The five leading faculties which solicit the will are sensations, thought, duty, and religion; and the conditions of harmonious development of the good (*l'amour du bien*) are self-control. His *Visateur du bien* received the prize of the Académie. In 1827 he published *De l'éducation des muets de naissance*; and in 1828 his *Institutes du droit administratif*, which was finished by Boulay-Latour. Shortly before his death he made a tour through Germany and Switzerland, in order to study the system of hospitals and charitable institutions.

(Gr. *κράνος*, a crane), the botanical name of the genus and the popular name of plants belonging to the *Geraniaceae*. Plants of the genus *Geranium* are perennials, biennials, or annuals; stems swollen at the joints; leaves divided and palmately lobed or dissected; stalks terminal or lateral, one-celled; flowers symmetrical, parts equal; stamens ten, in two series, the outer ones opposite the petals and alternating with the petals are five upon the receptacle; the pistil consists of two-ovuled carpels united to a common axis. As the pistil matures and the attached styles elongate, the jointed fruit about an inch and a half long acquires the beak-like character of the fruit, a popular name of cranesbill, and the botanical name for the genus also. When ripe the carpels break away from the axis, the small one-seeded pods reaching to the styles, the separation from below upward. Six species of cranesbill are found east of the Rocky Mountains and a few others are peculiar to the West of our territory. The only perennial eastern species, and at the same time the most common, is *G. maculatum*, spotted cranesbill, its stem is about 1 foot high, each of its numerous branches bears light purple flowers about an inch across; the leaves are about five-parted, with a notch at the ends; when old they are whitish blotched, on account of a very conspicuous character the

specific name was given. The root stock of this plant is very astringent, and is not only a popular domestic remedy in diseases of the bowels and other cases where astringents are required, but is official in the United States pharmacopœia. On account of its astringent

Spotted Cranesbill (*Geranium maculatum*).

is that it is in some places called alum-root, a name which properly belongs to *Heuchera*, and should be restricted to it. Of the annual kinds we have *G. Robertianum*, or herb Robert, a beautiful plant common in our woods, especially among rocks and in the rich black mould of their crevices, where it is partially shaded. Its flowers, though small, are numerous and

Herb Robert (*Geranium Robertianum*).

are prettily striped and rosy, and its foliage is so delicately cut and borne upon long slender petioles, that it is well adapted for the garden, especially in the rockwork. A heavy disagreeable odor is however emitted from its leaves, if handled. Frequently in the autumn

the leaves are curiously dotted with minute black specks, the perithecia of a parasitic fungus (*dothidea Robertianum*). *G. Carolinianum*, similar, with paler flowers and scentless foliage, erroneously supposed to be *G. dissectum*, occurs in waste places on barren soils, and is widely diffused. *G. pusillum* (small-flowered cranesbill), with slender stems, rounded, five-parted, kidney-formed leaves, and small bluish-purple petals, has been found in waste places in New York and Massachusetts. The last three are natives of Europe, naturalized in this country. Some exotic perennial species are cultivated in our gardens; the commonest of these is *G. sanguineum*, a native of England, with deep crimson-purple flowers which bloom nearly all summer; a variety of this is known as *G. Lancastriense*. *G. Ibericum*, *G. pratense*, and a few others are also grown. The anemone-leaved geranium, *G. anemonefolium*, is a greenhouse species, with beautifully divided leaves, from the Cape of Good Hope.—Geranium is the name popularly given to the species and varieties of *pelargonium*, so generally cultivated. The genus *pelargonium* differs from *geranium* in several characters, the most obvious of which are the half-shrubby character of the stems and the somewhat irregular flowers. One of the sepals or divisions of the calyx has its base prolonged, which runs down on one side of the pedicle or flower stalk as an adherent spur, as may be seen in a cross section of the pedicle; the two petals nearest this sepal are often different from the others in size and shape; stamens that bear anthers usually seven, always less than ten; pistil as in *geranium*. The name, as with *geranium*, is suggested by the fancied resemblance of the fruit to the bill of a bird, but in this case it is the stork in place of the crane (Gr. *πελαργός*, a stork). There are no more popular tender plants than the various *pelargoniums*, whether for window culture, summer bedding plants, or choice ornaments to the conservatory and greenhouse. Though the name *geranium* applied to them is incorrect, it has become so firmly attached by long usage that no change is probable. As with many other plants that have been long in cultivation, the *pelargoniums* have become so mixed by hybridizing, crossing, and sporting, that it is generally difficult to determine the species from which they originated. The Cape of Good Hope has furnished a large majority of the species, a few only having come from Australia and elsewhere. A scientific classification being impracticable, it will serve our purpose to group them after the manner of the florist. The scented *pelargoniums* include a number that have fragrant foliage and generally inconspicuous flowers. The best known is the rose geranium, *P. capitatum*, which is probably the oldest species in cultivation, it having been carried to England in 1690; its lobed, downy, pleasantly scented leaves are well known; there is a variety with the leaves edged with white. The peppermint geranium is *P. tomentosum*; the nutmeg-scent-

ed, *P. odoratissimum*; and the pennyroyal-scented, *P. exstipulatum*. The ivy-leaved *pelargoniums* form a very distinct group, distinguished by their smooth, fleshy leaves, like those of the ivy, and their weak trailing stems; they are mainly derived from *P. peltatum* and *P. lateripes*. Within a few years great improvement has been made in this class, and they now present a great variety in foliage and flowers; their prostrate habit especially adapts them to cultivation in window boxes and hanging baskets. Florists' *pelargoniums* or show *pelargoniums* as they are often called, have rounded leaves and flowers, often of a somewhat irregular, of the greatest beauty of color and markings; they have resulted from continued crossings, and their origin is not so secure that recent French writers name them all *P. hortulanorum*, the *pelargonium* of gardeners. This class is only seen in cultivation in greenhouses, and it requires great

Scarlet Geranium (*Pelargonium inquinans*).

and skill to make a fine show of them. They then have a large class that flower indoors in winter, and are turned out into the border in summer, where they are used in masses to produce fine effects by their flowers or foliage. The foliage of these has an unpleasant smell, and some of them are popularly known as *geraniums*. The old scarlet geranium, *P. quinans*, and the horseshoe geranium, *P. zonale*, are the principal species from which this class has originated; the flowers range from white to the most dazzling scarlet and dark crimson. Of late a number with double flowers have been introduced; their foliage is often highly ornamental, it being variegated with white, yellow, pink, and other shades. In the greenhouses, florists do not agree in classing these varieties; their principal ones are the noregay, zonale, bronze-

tricolors, and gold and silver margined. Some of the tricolors, of which "Mrs. Pollock" may be taken as the type, have leaves beautifully colored; but these do not flourish well in our hot summers, and are only seen in perfection when grown under glass. *Pelargoniums* grow

Horsehoe Geranium (*Pelargonium zonale*).

readily from seed, and if started early in a hotbed the plants may be had in bloom the same season; the plants have such a mixed and varied ancestry that seeds from almost any of our cultivated kinds are likely to produce plants different from the immediate parent.

Pin Grass (*Erodium cicutarium*).

Those who engage in the production of new varieties practise careful crossing, using the pollen of one variety upon the pistil of another in the usual way. The varieties are perpetuated by propagating from cuttings, which readily take root; the commercial florists propagate them

all winter for the spring sales; the amateur can readily multiply them in the open ground after the hot weather of summer is over. Cuttings two to six inches long, planted in a shady place, will soon take root and make good plants for winter blooming; if the stems from which the cuttings are to be taken are very succulent, they should be cut half or two thirds through, and when the wounded surface has dried the cutting can be entirely removed.—*Erodium* (Gr. *ἑρῶδιος*, a heron) is a genus closely related to *geranium*, from which it principally differs in having the leaves pinnately instead of palmately divided, and in the twisting of the styles when in fruit they break away from the beak-like receptacle. The plants are mostly natives of Europe and the East, and there is one species indigenous to Texas, *E. Texanum*. The only *erodium* of special interest is *E. cicutarium*, which is sparingly naturalized in some of the eastern states, and abundantly so on the Pacific coast, where it is of great service as a forage plant, its young growth furnishing a bite to the cattle when there is but little else for them to eat. It is known as pin grass, and also by the Mexican name of *ajfilaria*.

**GÉRARD**, the Blessed, a saint of the Roman Catholic church, and founder of the order of knights hospitallers of Saint John of Jerusalem. (See SAINT JOHN OF JERUSALEM.)

**GÉRARD**, Cécile Jules Baille, a French officer, born at Pignana, Var, June 14, 1817, drowned in Africa in September, 1864. Enlisting in the spahis, he landed in Africa in 1842, and two years later killed his first lion. In all he killed 25. On his return to France he gave the results of his experience in *La chasse au lion* (1855) and *Gérard le tueur de lions* (1856). The latter work has been translated into English under the title of "Gérard the Lion Killer." He afterward proposed to explore the Kong range in western Guinea, which had not yet been visited by any European. Starting from England in the latter part of 1863, he attempted to penetrate into the interior of Africa through Dahomey. Failing in this, he proceeded to Sierra Leone, whence an English man-of-war took him to the river Gallinas. He started again for the interior, but having been plundered of his baggage he resolved to return to Sierra Leone. While crossing the river Jong he was drowned.

**GÉRARD**, Étienne Maurice, count, a French marshal, born at Damvillera, April 4, 1773, died in Paris, April 17, 1855. He enlisted in 1791 as a private, served under Dumouriez and Jourdan, and obtained a colonelcy in 1800. He distinguished himself at Austerlitz, Halle, Jena, and Wagram, receiving as reward for his services the rank of general of brigade and a barony. After service in Portugal and Spain, he joined the Russian expedition, and as general of division evinced unfaltering energy during the retreat from Moscow. He was severely wounded in the campaign of 1813, and in 1814 fought successfully against the invading troops.

During the campaign of 1815 he was placed under the command of Grouchy, who had orders to prevent the Prussians from joining the English army under Wellington. On the morning of June 18, hearing the report of cannon, he strongly urged a march toward Waterloo, but was overruled. On the fall of Napoleon, Gérard left France, and did not return till 1817. In 1822 he was elected deputy, took his seat among the opposition members, and was reelected in 1823 and 1827. He contributed to the success of the revolution of 1830, and after being minister of war for three months, reentered the chamber of deputies. Having been promoted to the rank of marshal, he was in 1831 intrusted with the command of the French army sent to protect Belgium against Holland. In 1832 he commanded at the siege of Antwerp, which he forced to capitulate, Dec. 23. In 1834 he again held for three months the office of minister of war. He was made count in 1818, peer in 1832, grand chancellor of the legion of honor in 1835, commander general of the national guards of the Seine in 1838, and senator in 1852.

**GÉRARD, François Pascal Simon**, baron, a French painter, born in Rome in 1770, died in Paris, Jan. 11, 1837. He entered the studio of David in 1786; in 1792 he visited Italy, but soon returned, and exhibited in 1795 his first great picture, "Belsharius." "The Three Ages," "Cupid and Psyche," "Ossian," and the "Battle of Austerlitz," which appeared in succession from 1806 to 1810, established his fame. The last was applauded for its accuracy and beauty by Napoleon, who, as well as nearly all the members of his family, had their portraits painted by Gérard. At the command of Louis XVIII. he executed in 1817 his "Entry of Henry IV. into Paris." His "Louis XIV. declaring his grandson Philip of Anjou King of Spain" appeared in the public exhibition of 1828; and his "Coronation of Charles X." in that of 1829. Under Louis Philippe he executed various important works in the halls of the historical museum at Versailles and in the cupola of the Pantheon. The latter, completed in 1836, were the last of his performances. During his career, besides 30 historical pictures, some of which are of very large dimensions, he painted nearly 300 portraits.

**GÉRARD DE NEVAL** (GÉRARD LABREUNIE), a French author, born in Paris, May 21, 1808, died there, Jan. 24, 1855. He published when

18 years old a series of poems entitled *Élégies nationales*, and in 1828 a new translation of *Faust*. He wrote dramas either by himself or in conjunction with Alexandre Dumas, one of which, *Léo Burckart*, was published in 1831 with notes. In 1850, in conjunction with Méry, he produced *Le chariot d'enfant*, a metrical translation of an Indian drama, and a series of philosophical and biographical essays upon eccentric characters, entitled *Les illuminés, ou les précurseurs du socialisme* (1852). On the morning following the anniversary of the death of Jenny Colon, an actress whom he loved devotedly, he was found hanging and dead in the street.

**GÉRARDMER**, *Géromé*, or *Gérometz*, a town of France, in the department of Vosges, on the margin of Lake Gérardmer, near the German frontier, 22 m. S. E. of Épinal; pop. in 1901, 6,225. It covers a considerable extent of ground, the houses mostly standing in gardens. It has a large trade in cheese, known as *Géromé* cheese. Lake Gérardmer is the most beautiful of the inland waters of France; it is oval in shape, about 1½ m. long, and traversed by the river Valogne.

**GERASA**, or *Caesara* (now *Jerash*), a ruined city of Palestine, E. of the Jordan, in the ancient

The Little Theatre at Gerasa.

Decapolis, 55 m. N. E. of Jerusalem, on the opposite slopes of two hills, between which flows the river Keruan. The most interesting of its remains extend along the right bank of the stream, and comprise a Corinthian temple and triumphal arch, five or six other temples, and two theatres, all of marble; a *neanachie*, or artificial basin for the representation of sea fights; and a small temple, with a semicircular Ionic colonnade from which a street, lined with rows of columns, traverses the city. At right angles with this are three other streets, all full of relics of ancient greatness. There are raised walks for foot passengers on either side, while

entre-course still shows marks of chariot races. The walls, which are pierced by three arched gateways, and flanked by occasional towers, are in tolerable preservation. Outside is an extensive necropolis; 200 yards N. E. is a large reservoir, and near it can be traced an ancient aqueduct. The river and valley are crossed by several bridges. There are two grand baths, and inscriptions, chiefly of the time of Antonine Pius, but in general much defaced, are visible in all directions. Mention of Gerasa is first made by Josephus, who states that King Alexander Jannæus, after subduing Pella, attacked and captured it, about 85 B. C. It is mentioned by Greek and Roman writers, but details of its history are given. After the Arab conquests in the East the district around it became one of their favorite colonies. It was burned by the Jews at the commencement of their war with the Romans, and taken by Annianus, one of Vespasian's generals. A century later it attained its greatest prosperity. On the rise of Christianity it became the seat of a bishop. In 1122 Baldwin captured it and destroyed the castle.

**GERBOA.** See JERBOA.

**GERDIL, Hyacinthe Sigismund**, a Savoyard philosopher, born at Samoens, June 23, 1718, died there, Aug. 12, 1802. He became a Barnabite, studied theology in Bologna, won the friendship of Cardinal Lambertini, afterward Benedict XIV., and became professor of metaphysics at Macerata, at Casale, and finally Turin. Refusing the dignity of general of the order, he became tutor to the prince of Piedmont, afterward Charles Emanuel IV. of Sardinia, the rich abbey of Chiasso being given to him, whose revenues he devoted to charity. His first works were *Éclaircissements sur la vérité et la dicisibilité de l'étendue géométrique* (1741), and *Immatérialité de l'âme démontrée contre Locke* (1747). To these works succeeded almost every year until his death a volume in Latin, French, or Italian, on questions of theology, philosophy, physical or mathematical science, and sociology. He was made a cardinal *in petto* by Clement XIV., officially proclaimed as such in 1777 by Pius VI. Appointed prefect of the Propaganda, protector of the Maronites, and controller of oriental publications, he led in Rome a life of the most laborious poverty. He sold his library in 1798 in order to support himself, and fled to Siena, where Pius VI. to Siena, and would have been unanimously chosen by the conclave as successor, if the fact of his being a native of Savoy, then a part of France, had not been known to Austria to oppose him. His complete works were published in Rome (20 vols. 8vo, 1801-'21). An edition of his select works in French was begun in Paris in 1826, but only 2 vols. have appeared. In 1863 Migne published an edition of his theological works in 1 vol. 8vo.

**GERDY, Pierre Nicolas**, a French physiologist, born at Loches, Aube, May 1, 1797, died in Paris,

March 18, 1856. In 1834 he became professor in the Paris faculty of medicine, and in 1837 was elected a member of the academy of medicine. His treatment of physiology was systematic rather than experimental, and he carried to an extreme degree the doctrine of the so-called vital properties residing in as many different organs and tissues of the body, and accounted directly for the phenomena of life, without any reference to the action of physical or chemical forces. His publications were numerous and varied in character, most of them appearing in the medical journals or in the bulletins of the academy of medicine. He also wrote *Anatomie des formes extérieures, appliquée à la peinture, à la sculpture et à la chirurgie* (1829); *Traité des bandages et des pansements* (1837-'9); *Physiologie philosophique des sensations et de l'intelligence* (1846); and *Chirurgie pratique*, uncompleted (1851-'5).

**GERFALCON**, or *Jerfalcon*. See FALCON.

**GERHARD, Eduard**, a German archæologist, born in Posen, Nov. 29, 1795, died May 12, 1867. Resigning a professorship at Breslau on account of weak eyes, he travelled in Italy, and resided 15 years in Rome. He was engaged on Platner's *Beschreibung der Stadt Rom*, planned by Niebuhr, and then directed by Bunsen, for which he undertook to furnish a complete account of the sources of knowledge concerning ancient Roman topography, under the title of *Scriptores de Regionibus Urbis*. When in 1828 the crown prince of Prussia visited Italy, Gerhard accompanied him to Naples, and obtained his protection for the *Instituto di corrispondenza archeologica*, founded at Rome, of which Gerhard was director until his return to Prussia in 1837. He was afterward appointed archæologist of the royal museum at Berlin, professor in the university of that city, and member of the academy of sciences. Among his numerous writings are: *Antike Bildwerke* (Stuttgart, 1827-'44, with 140 copperplate illustrations); *Auserlesene Griechische Vasenbilder* (4 vols., Berlin, 1839-'58, with 380 plates); *Griechische und Etruskische Trinkschalen* (1840); *Etruskische und Campanische Vasenbilder* (1843); *Trinkschalen und Gefässe* (2 parts, 1848-'50); and *Ueber die Hermenbilder auf Griechischen Vasen* (1856).

**GERHARDT, Charles Frédéric**, a French chemist, born in Strasburg, Aug. 21, 1816, died there, Aug. 19, 1856. The son of a manufacturer of chemical products, he studied in 1835 in Liebig's laboratory at Giessen, and in 1844 was appointed professor at Montpellier, where he remained four years. He returned to Paris and established a private laboratory, in which he continued his researches till 1855, publishing papers upon homologous series, the theory of types, the anhydrous acids, and the starches. In 1855 he accepted the chair of chemistry and pharmacy at Strasburg. Among his most important publications is the *Traité de chimie organique* (4 vols. 8vo, 1853-'6), upon which he was occupied a large portion of his life, and in

which he presents a complete account of the actual progress of organic chemistry. The work was intended as an appendix to Berzelius's *Chimie minérale*.

**GERHARDT, Paul**, a German poet and theologian, born at Gräfenhainichen, near Wittenberg, March 12, 1607, died at Lübben, June 7, 1676. Little is known of his life till in 1651 he became pastor at Mittenwalde, a position which he exchanged in 1657 for that of deacon in the church of St. Nicholas in Berlin. He was there at the head of the strict Lutherans against the syncretism of Calixtus and his followers, and was deprived of his diaconate because he refused to obey the edict of 1664 forbidding either party to defame the other in the pulpit or tax it with heresy. In January, 1667, he was reinstated in his office, but resigned the following month, and in 1668 became arch-deacon in Lübben. He is esteemed the author of the best German hymns after those of Luther; several of them were translated by John Wesley, and are found, in part at least, in the Methodist hymn book. In Germany they were first collected under the title of *Geistliche Andachten in 120 Liedern* (Berlin, 1666), and many of them are contained in most of the Protestant hymn books in Germany. Of their numerous editions, the best is that of Philipp Wackernagel (Stuttgart, 1843).

**GÉRICULT, Jean Louis Théodore André**, a French painter, born in Rouen in 1790, died in Paris, Jan. 18, 1824. He was a pupil of Carle Vernet and of Guérin, and his first pictures, the "Guide of the Imperial Guard in 1812" and the "Wounded Cuirassier," were well received. In 1816 he went to Italy, and in 1819, on his return to France, he exhibited the "Raft of the Medusa," a very dramatic scene, executed in the most powerful style, which is considered one of the masterpieces of the French school.

**GERLACH, Otto von**, a German theologian, born in Berlin in 1801, died there, Oct. 24, 1849. He held various ecclesiastical offices, and not long before his death became professor at Berlin. He published several works, prominent among which are a commentary on the Scriptures, known as the *Gerlach'sche Bibel*, which was continued after his death by Schmieder. He also edited *Anzahl von Luthers Schriften* (24 vols., Berlin, 1840-48).—His elder brother, **ERNST LUDWIG**, born in Berlin, March 7, 1795, is prominent as an ultra-conservative journalist and politician, and as the parliamentary leader of the high-church party in Prussia.

**GERMAN CATHOLICS** (*Deutschkatholiken*), a religious denomination, formed in 1844 by secession from the Roman Catholic church of Germany. It owed its origin mainly to a letter written Oct. 1, 1844, by Johannes Ronge, an excommunicated priest of Silesia, to Bishop Arnoldi of Treves, in which the exhibition of the holy coat of Treves was called an idolatrous festival, and the bishop was called upon

to suppress it. In the Prussian province of Posen another Catholic priest, Johann Czerski, had already declared on Aug. 22 his secession from the Roman Catholic church, and had attempted the foundation of a Christian Catholic congregation. After the publication of the letter of Ronge these two united a number of congregations, who called themselves German Catholics, sprang up in a short time. The "Confession of Schmühl," drawn up by Czerski, rejected reception by the priests alone of the Lord's Supper in both kinds, the canonization and invocation of saints, indulgences and fasting, the use of the Latin language in service, the celibacy of priests, the prohibition of mixed marriages, the supremacy of the pope and other points. They retained sacraments and the mass, which they celebrated in the vernacular language. The "Confession of Breslau," which set forth the views of Ronge, also claimed free interpretation of the Bible and freedom of belief for every individual member. A council which met at Breslau on March 22, 1845, adopted a new creed based on the "Confession of Breslau." At this time the principles of German Catholicism spread very rapidly. The attitude of the governments with regard to it was very different. In Austria and Bavaria it was even prohibited to use the name. A serious obstacle to the growth of the new religious denomination was found in their internal dissension, which had been from the beginning a radical one between Ronge and Czerski. The latter was in general with the doctrines of orthodox Protestantism, while the former was in opposition to all the views of the Protestant church. Czerski issued a circular ("New Confession of Schmiedemühl") against those who denied the divinity of Jesus Christ. An attempt was made by the two parties on a compromise, which was made in an assembly at Rawicz, but it had not the desired effect. The conferences of 1848 seemed to be very favorable, but some additions were made to their confessions in Austria and Bavaria; but the suppression of German Catholicism was prohibited in those countries. The synod of Leipzig, which met in May, 1848, was transferred to Köthen on account of the interference of the police; it proposed a union with the Free congregations, which refused themselves by secession from the Roman Catholic churches, and the election of a committee from both to act as a presiding bureau for a triennial diet, which was proposed but it did not meet. In 1850, the representatives of the German Catholic congregations met at Breslau, but between the two parties was no union. In 1862, however, they were united in the majority of the German Protestant churches.

history of German Catholicism is given by Kampe, *Geschichte der religiösen Bewegungen der neuern Zeit* (4 vols., Leipzig, 1852-'60).

**GERMANIC RACES AND LANGUAGES.** Before the political history of Germany began, or a distinct German nation appeared, Germanic races moulded the political organizations of the north and west of Europe, and Germanic languages either superseded or modified the speech of the previous inhabitants. Ethnologists sometimes classify the Germanic races under the generic name of Teutons, as a main division of the Slavo-Germanic branch of the Aryan or Indo-European family of nations. The term Teutonic, in this wider sense, is chiefly used by English writers, as the equivalent of the German *Germanisch* (Fr. *germanique*), in contradistinction to *Deutsch* (Fr. *allemand*), in the narrower sense, and is thus often used in this work. They distinguish three groups: Scandinavians, Goths, and Germans. The Scandinavians occupy Norway and Sweden (excepting the territory of the Lapps), the Danish isles, and the peninsula of Jutland. The Goths, now extinct, were subdivided into Ostrogoths and Visigoths, or Eastern and Western Goths. The Germans are subdivided into two groups, the northern and southern, or Low and High Germans, and are found principally in Germany, the Netherlands, England, the United States, and the British colonies. There are many hypotheses in regard to the meaning of the word German. Some authorities derive it from the old High German *ger*, spear or javelin, and consider the *Germani* of the ancients as the equivalent of *Germanen* or men armed with such weapons. Others derive it from the Celtic *gairm* or *garm*, noise, and understand it to refer to the ancient German practice of shouting in battle. The modern German word *Deutsch* is held by some to be a modification of the name Teut, Tuisco, or Tuisto, a mythical ancestor of the Germans; others trace it to *diet*, old High German *diot*, pertaining to the people, or national; and others again to the verb *dintan*, to explain. The cradle of the Indo-Europeans is generally placed in Asia, whence the Germans have been supposed to have entered Europe across the Ural and Caucasus. Some recent authorities, however, remove the primitive habitat of the Aryans from the sources of the Oxus and Jaxartes to the Russo-Lithuanian plateaus, contiguous to the first historical habitat of the Germans, north of central Europe, and within the boundaries of the Rhine, the Danube, and the Vistula. There are no positive data about the Germanic races prior to the 2d century B. C. No mention is made of them when the Hellenes came in contact with the Scythians, and the Gauls carried terror to Rome and Delphi. Pytheas of Massalia met with Goths and Teutons on the Baltic, and it is probable that the Goths inhabited Scandinavia before the 4th century. Arrian says that Alexander the Great had dealings with peoples living on the lower Ister (Danube),

whom he calls Celts; but he mentions the Germanic Quadi and Marcomanni as tribes of them. It is evident that the Greek writers often speak of Germans as Celts or Galatians. Strabo designates the Germans as Celto-Scythians, meaning a people neither Celtic nor Scythic. The uncertainty of the Greek and early Roman writers concerning them renders it presumable that the Germans lived before the time of the Cimbric migrations isolated from their neighbors to the south and west, while the correlation of the two linguistic groups seems to indicate that they lived in constant intercourse with the Slavs. In the 2d century B. C. the Germanic races became the dominant element in western and central Europe. The first historical migration started from the Cimbric peninsula, whence the tribes composing it were indiscriminately called Cimbri. Other migrations of the same period took their rise in the region of the Baltic, and the name of Teutons was given to the tribes figuring in these. The Celts previously moved to the west and south, but many of them had retraced their steps, and migrated with Germanic races from west to east. This mixed people appeared under Cambaules and Cerethrius in Thrace, and after the dissolution of the Macedonian empire under Brennus in Macedonia and Greece, and under Leonnarius in Asia Minor. The torrent of Cimbri and Teutons which rushed over the Alps at the close of the 2d century B. C. failed to weaken the Romans in the mountainous districts of northern Italy and Illyria. Germanic tribes were for centuries put to their utmost to prevent the further advance to the north of their southern enemies. Caesar and Tacitus are the most valuable authorities upon the condition of the western districts of Germany in their time. Caesar states that the Rhine was the eastern boundary of Gaul, and affirms that in Switzerland, southern Alsace, near the upper Moselle, and on the shores of the strait of Dover, there were only four Celtic tribes, the Helvetii, Sequani, Mediomatrici, and Morini. He called the country of the Maas, north of Sedan, Germania Inferior, and the left bank of the Rhine, between Breisach and Linz (near Coblenz), Germania Superior. Tacitus divides the Germans into three classes, which he says were the descendants of the three sons of Mannus, the son of Tuisto, a god whom all Germans adored. He names Ingævones as living close to the sea; Hermiones inhabiting the centre; and all others were Istævones. He mentions also as original divisions, according to some, the Marsi, Gembrii, Suevi, and Vandals. Pliny the Elder knew five principal divisions of Germans: Vindili, Ingævones, Istævones, Hermiones, and Peucini. The Germanic races formed confederations at a very early period. The most ancient known were the confederation of Suevi, described by Caesar; another of Cherusei, founded by Arminius; and a third of Marcomanni, with Marbodius as chief. The Batavi settled on the banks of the

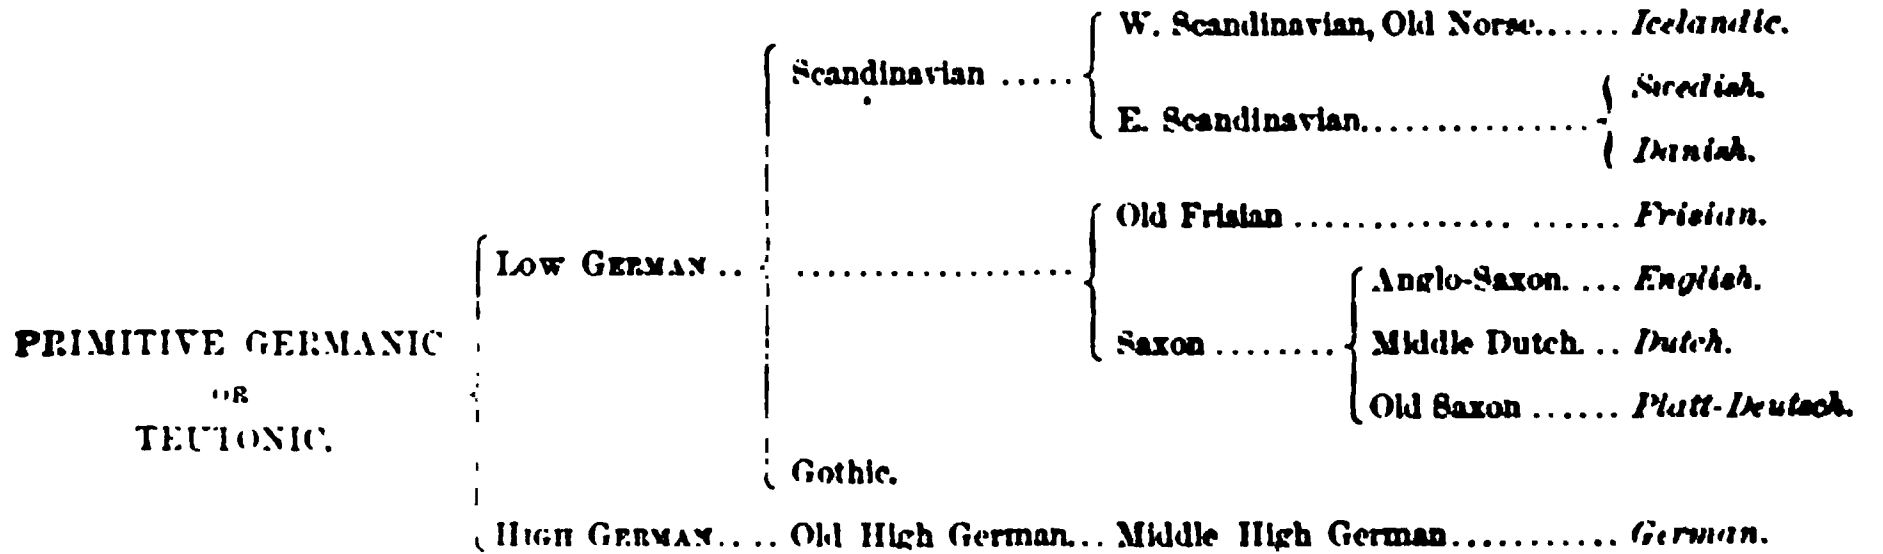

Rhine, around the lowest portion of its course, the Ubii near Cologne, the Treviri near Treves, the Nervii in Hainaut, the Vangiones near Worms, the Nemetes near Spire, and the Tribocci in Alsace. Between the Rhine and the Elbe lived the Catti (Hessians), with the Usipii N. of the Lippe, the Sigambri and Tencteri between the Ruhr and Sieg, the Cherusci around the Hartz, the Bructeri in Westphalia, and further north the Chamavi and Angrivarii. Between the Weser and the Ems lived probably the Dulgibini and Chasuari mentioned by Tacitus. On the shores of the North sea were the Frisii and Chauci, and on those of the Baltic the Heruli and Rugii. On the lower Elbe lived the Saxons, with the Angles S. E. of them; higher up on the west bank of the river, the Longobards. On the Danube, and subsequently in Bohemia, were the Marcomanni, and E. of them the Quadi. In Silesia dwelt the Semnones, Lygii, and Burgundians, and between the Vistula and the Pregel, the Goths. The name of Suevi was given to a confederation of tribes scattered over the territory between the Elbe, the Vistula, and the Baltic. This confederation reached subsequently to the southern portions of Germany, where its name Swabians (*Schwaben*) is still current. It is impossible to state the precise limits of the different tribes. There was a constant shifting of settlements, and the subsequent migrations have rendered the boundaries of Tacitus totally undistinguishable. The southward pressure of the Germans, Slavs, Finns, Huns, and Avars commenced in the 3d century A. D. The result was the withdrawal of the Romans from the southern portion of Germany, and the loss of the eastern portion to Slavic and Finnic tribes. The Longobards settled for a while in the north of Hungary, the Gepidæ in the east of it, the Goths in Mæsia and Illyria, the Marcomanni in Vindelicia and Noricum, the Alemanni and Burgundians in Helvetia. The whole original territory from the mouth of the Danube to the delta of the Rhine was thus occupied again by Germanic races. But the pressure of the eastern races continued, and impelled by it about one half of the German warriors attacked the Roman empire, and divided southern Europe among them. The whole Gothic family of Vandals, Heruli, Rugii, Gepidæ, Alani, Suevi, Longobards, Burgundians, and Franks left Germany almost entirely, and the Slavs and Finnic races took possession of the thinly populated districts, and extirpated in several places the German inhabitants. The Gothic empire on the Danube, founded there after the exodus of the Goths from the Baltic territory, was conquered by the Huns. After Attila's death the Goths separated again into the old divisions of Eastern and Western Goths. The Visigoths were led by Alaric to Italy (about 400), and by his successor Ataulf to Spain, and became Romanized. Theodoric led the Ostrogoths to Italy (489), where he founded a mighty empire, which after his death was absorbed by the Byzantines.

The people disappeared in the small that survived the disasters of the 1. The Burgundians moved to the Rhine Neckar, and subsequently into R where they settled between the Rhône, and founded an empire, conquered and absorbed by the F 534. They too became Romanized. dals moved from the Oder and V Early in the 5th century they c and Genseric took them to Afr founded an empire, which was Belisarius in 534, when the Vandals The Scandinavians remained in isolation. The Goths inhabited portion of the Scandinavian peninsula no further north than the lakes Wener, and Hielmar. From the population Jutland went forth the stock of the speaking race. During the 5th centuries three Germanic tribes, the Angles, and Saxons, crossed the North Sea settled in the British islands, and former population. The country and the Weser then became the main place of pure Germanic elements. The pal races in the old homestead were Saxons, Thuringians, Franks, and and they were in danger of b the Slavs. Charlemagne succeeded in the Wends back to the Vistula, the the Oder, the Czechs to the lower C and the Croats as far as Spalato and also in destroying the Avar nonia. The Moors had destroyed of the Visigoths, and the Frankish sorbed the other Romano-Germanic the exception of small fractions in empire comprised the whole of ( many as far as the Oder, and a was found necessary to frai the Romance and the German portion which Louis the Great the division of the East Fr embraced all the pure Germanic ing those on the Maas a earliest record of the existence of a national language dates from (lingua Theutisca, Theotisca, Theodisca), and the development nation as a blending of several belongs to the Henry I. subdued eastern Franks or and under Otho I. a During this period the the Faroe and Sh and Hebrides, Ice ited the north coast of the They established the isles and France (Northmen) sions produced however cept in Iceland and the Northmen of Norway went to Italy, the Two Sicilies,

1066. The Danes moved south on the peninsula of Jutland as far as the Schlei, but their invasions of England, prior to the Norman conquest, proved fruitless in the end. The Swedes were similarly unsuccessful in Esthonia and Livonia, but their conquest of Finland led to a lasting establishment of their nationality on the European mainland, which the Russian occupancy of the country since the beginning of the 19th century has not been able to efface. The history of the German empire after Otho I. is a series of contests between the emperors and the dukes of the principal races composing it. The Saxons, the Franconians, and the Swabians were in turn at the head of the empire in the persons of their own leaders. The political significance of special races ceased in the 13th century, but in language and manners there are still five which may be clearly distinguished. The Saxon race is dominant in the northwestern lowlands of Germany, especially in the northern districts of the Elbe, across the Hartz to Cassel, and across the Weser to the mouth of the Rhine. The Frankish race extends from the Fichtelgebirge to Treves, and from Hesse to the Raue Alp. The Thuringians inhabit the section between the Thuringian forest and the Hartz, and from the Werra far into Brandenburg. The Swabians live between the central Neckar and the Alps, and from the upper Rhine to Augsburg. The Bavarians reach from Augsburg to Vienna, and from the Fichtelgebirge to the Tyrol.—The boundaries of the modern German language are not coincident with the limits of the present German empire. In the northwest, German is spoken in some portions of the French department of Le Nord, the south and east of Belgium, and the eastern portion of the Netherlands. In the southwest, German is heard as far as the Doubs, the eastern Jura, the lake of Neuchâtel, and Monte Rosa in Italy. In the south, the language reaches from Monte Rosa to Mount St. Gothard, and thence almost directly east as far as the Mur in Styria. In the

east, the line may be drawn from Radkersburg on the Mur, through Presburg in Hungary, to Pöhlritz on the Iglau in Moravia, thence to Krümmau on the Moldau in Bohemia, and thence again to Taus. Further N. E. the territory of the German language reaches to Leitmeritz on the Elbe, and to the sources of the Oder in Austrian Silesia, whence the boundary runs directly N. to Krotoschin in Posen, and thence indefinitely to Interburg in East Prussia and N. W. to the Kurische Haff. The N. boundary follows the Baltic from Polangen to Flensburg in Schleswig, and the North sea from Tondern to Gravelines. It is possible to distinguish about 20 different dialects within this territory. They may be divided into Low German and High German dialects, of which the latter may be subdivided into South German and Middle German. Since the time of Luther these historical peculiarities of speech have however in a great measure disappeared, and are heard only among the lower classes.—LANGUAGES. Of all the numerous Teutonic tongues of ancient times, only five languages, German, Dutch, English, Danish, and Swedish, are now in a flourishing condition. Linguists consider the Scandinavian, Gothic, and German forms of speech as descended, in common with the modern idioms of India, Persian, Greek, Latin, Celtic, Slavic, and Lithuanian, from a single parent tongue, Sanskrit. It was, however, deemed necessary to go further, and to derive the whole group of Indo-European tongues from a primitive language, which was also the mother of Sanskrit. This language, of which no monuments exist, has been constructed by the science of comparative grammar, not as the primitive tongue from which all forms of speech are derived, but as one of many primitive languages, and as the parent of Sanskrit, Greek, Latin, Gothic, &c., as Latin is the mother of French, Italian, and Spanish. The following table exhibits the probable course of development of the Teutonic tongues:

Among the Indo-European languages, Gothic diverges widely from the primitive tongue, and must be considered as a younger sister of Sanskrit. Gothic was not the oldest of the Germanic tongues, though its literary documents date back further than any other. Old High German, old Norse, Anglo-Saxon, and Gothic

were probably sister dialects; at least no one of them appears to be derived from any of the others. Old High German comprises a number of dialects which were spoken chiefly in South Germany, as the Thuringian, Frankish, Swabian, Alsatian, Swiss, and Bavarian. They are found in literary records dating

from the 8th to the middle of the 11th century. A gradual change took place subsequently in the language, and it became the mother of a new dialect, which is called the middle High German, and which survived it in the same districts of upper Germany. The literature of middle High German reaches from the 12th to the end of the 15th century, and it is so clear, grand, refined, and melodious, that it has been called the first classical period of German literature. A new modification of the old High German, and a daughter of the middle High German, made its appearance for the first time in a literary production of note in Luther's translation of the Bible, and in its rapid development seems to have reached its culminating point in the literature of the present century. Under the term Low German are comprised all the dialects spoken in the lowlands of Germany. The old Saxon, which belongs to this group, was spoken between the Rhine and the Elbe, in the districts which lie at the foot of the central plateau of Germany. Its literary documents date from between the 9th and 11th centuries, and had their origin in the districts of Münster, Essen, and Cleves. The old Saxon is the mother of the middle Low German, which is to be distinguished from the middle German and middle Netherlandish or middle Dutch, and also from the modern derivative of it called modern Low German, or Platt-Deutsch. While old Saxon most closely approaches old High German, the dialect spoken in the districts of Thuringia and the region between upper and lower Germany formed a kind of transition between High and Low German. On the N. coast of Germany, between the Rhine and the Elbe, and beyond the latter river as far as Jutland, extended the old Frisian dialect. Its literary records are of comparatively late date, but it displays a very antique cast, resembling most closely the old High German. The Dutch language has no literature earlier than the 16th century, but it is still a literary and national language; while Flemish, which was also used during this period in the courts of Flanders and Brabant, had to give way to the official languages of Holland and Belgium, and its use is almost completely confined to the Flemish peasantry. Anglo-Saxon is also a Low German dialect. The four Germanic tribes that invaded Britain have left no record in the dialects peculiar to each, and there are no facts from which to determine the precise nature of their speech. The Jutes who settled in Kent, Hampshire, and the Isle of Wight probably did not speak an old Norse dialect, as no traces of it are found in those districts. The Angles, coming from a settlement adjacent to the Saxons, may also have spoken a Saxon dialect. The Saxons of England called themselves simply Saxons, in distinction from the old Saxons, or those who had remained on the continent; but it is still doubtful whether they belonged exactly to one and the same tribe. The term Anglo-Saxon

ever applied to all Germanic dialects in England after the 5th century. The e of the period extending to the end of 11th century is distinguished as old Anglo-Saxon with two principal dialects, the Saxon Anglian, or southern and northern, of which the Anglian or northern was the most influenced by Norse influences. The language of the subsequent period was a strange mixture of Old-Saxon with the Norse of the Danes and Swedes, and the Norse-French of the Norman conquerors; and the literary documents are characterized by a considerable loss of inflectional forms. Modern Anglo-Saxon English is divided into three periods: old English, middle English, and modern English. Old English continued to disregard the old inflectional forms, especially in the declension of nouns. Middle English is characterized by almost total absence of declensions of nouns and adjectives, and a great diminution of verb forms. Modern English continued the declension, and has now been stripped of all inflectional forms with the exception of the *s* and *ed* and *en* of the present tense, the *ing* of the present participle, the genitive and plural, the degrees of comparison of adjectives and adverbs, and a few inflectional cases. Old Norse is the dialect from an unknown period to the 11th century spoken in Sweden, Norway, Denmark, and adjacent islands. It is believed that it split at a very early date into two sister dialects, the mother of old Norse or Icelandic, and the parent of Swedish and Danish. The first germs of Swedish and Danish are considered to have existed long before the 11th century in the dialects of the Scandinavian

tribes. Swedish scholars distinguish between the East and West Scandinavian, which division they consider as having taken place before the Northmen settled in Norway and Sweden. The stationary existence of the Norse language in Icelandic, in which it has been preserved almost intact to the present day, is explained by the secluded position of the island, and the zeal with which the old songs and sagas, as collected and fixed in the two Eddas, have been cultivated by the inhabitants.—In regard to the degree of relationship in which these languages stand to each other, and in which they stand collectively to cognate languages, the six old Teutonic tongues may be classified in three groups: 1, the Low German, with the Gothic and its nearest relatives Anglo-Saxon, old Saxon, and old Frisian; 2, the old High German; 3, the old Norse. The affinities between these languages and the modern tongues derived from them are illustrated in the foregoing table. The first ten cardinal numbers have been chosen for this purpose, as numerals are preferable for comparative purposes to any other class of words on account of the invariableness of their meaning. The Latin, Greek, and Sanskrit forms have been added to show the degree of relationship of the Germanic to the cognate groups of the Aryan or Indo-European family of languages. The primitive tongue is understood to be the mother of all, and gives the forms from which linguistic scholars derive those of the most ancient as well as of the modern Aryan dialects. The changes which the words have undergone in these languages have been discovered to appear in each according to fixed principles, which in linguistic science are known as Grimm's law.

is stated by Max Müller as follows: "The same roots or the same words exist in Sanskrit, Greek, Latin, Celtic, Slavonic, German, Gothic, and High German, then the Hindoos and the Greeks pronounce an aspirate, the Goths and the Low Saxons generally, the Saxons, Anglo-Saxons, &c., pronounce the corresponding hard check. . . . Secondly, if in Greek, Sanskrit, Lithuanian, Slavonic, and we find a soft check, then we find the corresponding hard check in Gothic, a corresponding breath in old High German. . . . when the six first named languages show a hard consonant, then Gothic shows the corresponding soft check, old High German the

corresponding soft check." In illustration of the different formulas we add examples for each class and division. 1. Sansk. *hānān*, Gr. *χέν*, Lat. *anser* (= *hānsēr*), Goth. *gana*, O. H. **GERMANICUS CÆSAR**, a Roman general, born in Rome, 15 B. C., died near Antioch in A. D. 19. He was the son of Claudius Nero Drusus and Antonia, the daughter of the triumvir Antony, and was adopted by his uncle Tiberius in accordance with the will of Augustus. His original names are unknown. In 7 he accompanied Tiberius against the rebels of Dalmatia, served with distinction during three campaigns, and on his return to Rome received a triumph and the hand of Agrippina, granddaughter of Augustus. At the close of another campaign, in 11, he was made consul, and in the following year was placed in command of the eight legions on the Rhine. He was absent in Gaul when upon the death of Augustus (14) a universal sedition broke out in the army. He was a favorite with the soldiers, and they had already determined to raise him to the head of the empire, when he suddenly returned to the camp, and at the peril of his life succeeded in repressing two successive revolts, and in establishing Tiberius upon the throne. He immediately marched the pacified legions against the enemy across the Rhine, and routed the Marsi, whom he fell upon by night as they were celebrating a festival. Being soon after appointed commander-in-chief of all the legions of Germany, he began that series of exploits which gained him

his title of Germanicus. He marched against the native hero Arminius, the conqueror of Varus, defeated him, and made his wife Theselda prisoner; then penetrated to the Teutoburg forest, near the sources of the Lippe, the scene of Varus's disaster, and buried the bones of the legionaries who had fallen there. Yet Arminius hovered about the Roman army in impracticable places, attacked it in a narrow pass, and drove it into a marsh with so great loss that Germanicus decided to retreat to the Rhine. In the year 16 he returned against the Germans with a fleet of 1,000 vessels, landed at the mouth of the Ems, crossed the Ems and the Weser, and defeated Arminius first on the plains of Idistavisus and then in the vicinity of Minden. He determined thereupon to return, but he lost a part of his fleet in a storm, and his own vessel stranded on the shores of the Chauci. Fearing that his losses might embolden the Germans, he sent Silius against the Catti, while he himself attacked the Marci. He purposed to pursue his advantages in the following year, when Tiberius, jealous of his fame, recalled him, and in the triumph which was granted him Theselda figured among the captives. To rid himself of Germanicus, the emperor sent him to the East to fight the Parthians and to pacify Armenia. He at the same time gave the government of Syria to Cassius Piso, with secret instructions to thwart and annoy Germanicus. The latter hastened to Armenia, and placed the crown upon Zeno. He subsequently reduced Cappadocia to a province, and gave the command of Commagene to Servæus. At the request of Artabanus, king of the Parthians, he removed Vonones, the deposed monarch, to Pompeiopolis. In the year 19 he visited Egypt without the special permission of the emperor, as required at the time of his return to Syria; he suddenly fell ill, and Agrippina brought his ashes to Italy, where universal mourning; honors almost unequalled in Roman history were paid to him. Germanicus and Piso, accused by the emperor, were both poisoned, and Germanicus, anticipating his death, wrote a voluntary death. Germanicus is described in the "Annals" of Tacitus as one of the noblest characters in the history of the Roman empire. He had reputation as a soldier, statesman, and poet, but of several works which he composed there remains only a Latin version of the *Phænomena* of Aratus, which was the father of the emperor.

**GERMAN IVY** (*senecio scandens*), a climbing plant cultivated for its quick-growing habit, but which is not properly a true ivy. It is one of the composite family, and is found at the Cape of Good Hope. Its twigs grow to the height of 8 or 10 ft., and are covered with round heart-shaped leaves, each with several pointed lobes, of a dark green color, and a light green color. The flowers are seen in bloom, but it is not a true ivy. It forms bell-like clusters of

rs readily from cuttings, flourishes well in a dry atmosphere of dwelling rooms, and is admirably adapted to window culture; in the

German Ivy.

round it is a useful climber where it is left to cover a surface quickly, but it is killed by the first frost.

**GERMAN OCEAN.** See **NORTH SEA**.

**GERMAN SILVER**, or *Argentane*, an alloy resembling silver, made of variable proportions of ingredients according to the uses for which it is designed. A composition of 8 parts each of nickel and zinc is recommended as making a close imitation of silver. The two latter metals are also used in proportions of 4 each to 8 of copper. By a larger proportion of copper the alloy is easily rolled into plates, but the copper becomes apparent in use. Iron used in a proportion of 2 to 2½ per cent. renders the position whiter but more brittle. The German silver, made from the original ore at Harburg in Henneberg, analyzed by Berthel, was found to consist of copper 40.4 pt., nickel 31.6, zinc 25.4, iron 2.6.

**GERMANTOWN**, formerly a post borough of Philadelphia co., Pennsylvania, 6 m. N. W. of Independence, Philadelphia, and included 1854 in the 22d ward of that city; pop. 1870, 22,605. It has one main street about 4 m. long, extending S. S. E. and W. W. W., which is intersected at right angles by several others. It is lighted with gas, is supplied with water, and is connected with Philadelphia by both a steam and a horse railway. Many retired merchants and wealthy families of Philadelphia have here their residences, some of which are of great elegance. Among the public buildings are 21 churches, an academy and other schools, and a bank. There are also a number of extensive manufactures.—Germantown was laid out in 1684 under a grant from William Penn, and settled by

Germans, whence its name. It is memorable as the scene of the defeat of the American army under Washington by the British on Oct. 4, 1777. Washington, having learned that Gen. Howe had detached a portion of the main division of his army, then at Germantown, determined to take advantage of it to attack his camp. After marching all night, he entered the town about sunrise. The enemy, who were encamped across the main street at right angles, were taken by surprise, but the morning being dark and foggy, the Americans were thrown into confusion by the many small enclosures of the village, and the British rallied and attacked in turn. Some of the Americans were seized with a panic, and what had promised to be a victory was changed into a defeat. Washington withdrew in good order, with all his artillery. The British loss was upward of 600; the American about 1,000.

**GERMANUS** (Fr. *St. GERMAIN L'AUXERROIS*), a saint of the Roman Catholic church, born in Auxerre, central Gaul, about 380, died in Ravenna, July 31, 448 or 449. He was of a senatorial family, studied literature and jurisprudence, and distinguished himself for eloquence. He was made by the emperor Honorius military governor of his native district, and in 418 was elected bishop of Auxerre, although a married man. He separated from his wife, gave his property to the poor, and built a monastery on the river Yonne. He twice visited England at the request of Celestine I., and by his authority the doctrines of Pelagius were condemned and suppressed there, and schools for the education of the clergy were opened. He once led the Britons against a party of Picts and Saxons who were plundering the coast, and terrified them into retreat by a general shout of "Hallelujah," an action known under the name of the Hallelujah victory. He encouraged St. Patrick to undertake the conversion of the Irish, and in 447 went to Ravenna to mediate between the revolted Bretons and Valentinian III. His feast is celebrated on July 31. A manuscript preserved in the abbey of St. Gall, entitled *Liber Sancti Ambrosii in Laudem Sanctorum compositus*, is said by the Benedictine editors of St. Ambrose to have been probably written by St. Germanus. His life, written 30 years after his death by the priest Constantius, and put in verse by the monk Eric, is to be found in Labbe's *Nova Bibliotheca Manuscriptorum*. A new life of St. Germanus was given in vols. ix. and xi. of Newman's "Lives of the English Saints" (London, 1844).

**GERMANY** (Ger. *Deutschland*; Fr. *Allemagne*), formerly a large empire of central Europe, with an area at the time of the first French revolution of 267,714 sq. m., and 26,265,000 inhabitants. From 1806 to 1815 it was dismembered and disorganized. In 1815 the German confederation (*Deutscher Bund*) was established in the place of the old German empire, embracing part of Austria (the present

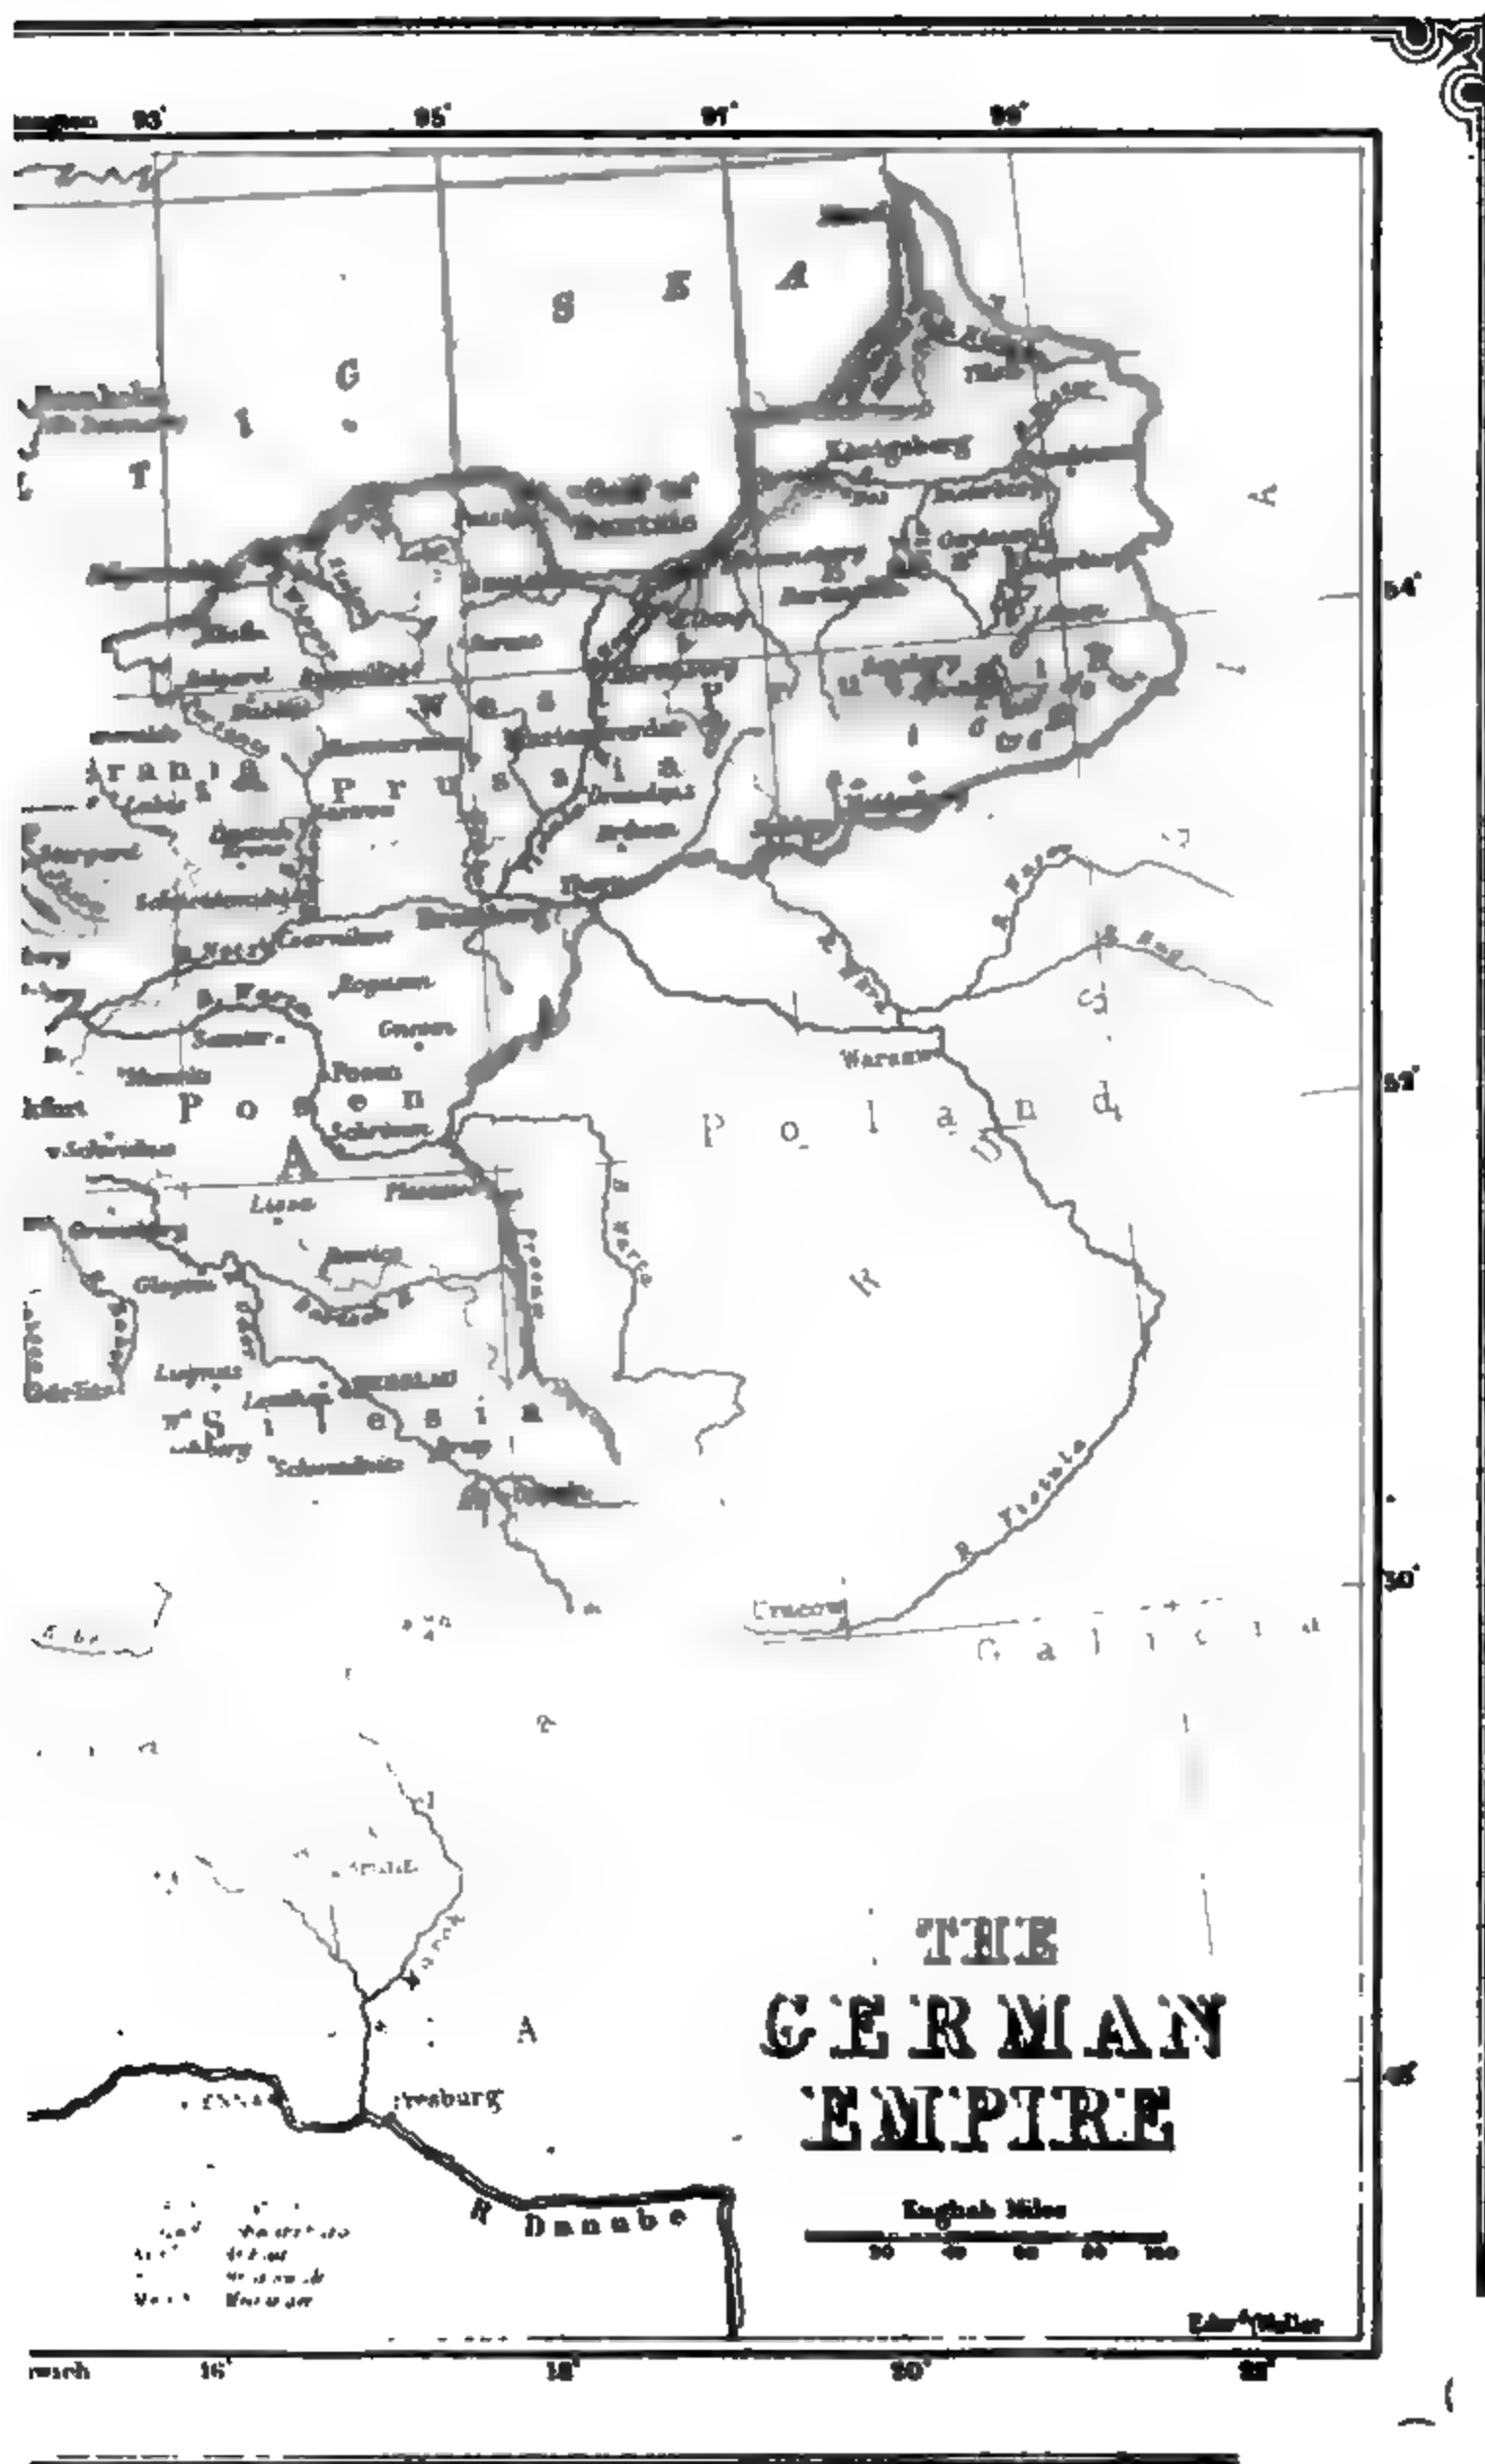

Cisleithania, with the exception of Galicia and Bukowina; see AUSTRIA), the bulk of Prussia (with the exception of Prussia proper and Posen), the kingdoms of Bavaria, Württemberg, Saxony, and Hanover, the electorate of Hesse-Cassel, and a number of grand duchies, duchies, principalities, and free cities; in all 39 states, which in 1866 had been reduced to 33. The area of this confederation was 243,539 sq. m.; the population in 1865, 46,412,536. In 1866 it was dissolved. Austria was excluded from Germany, and Hanover, Hesse-Cassel, Nassau, and Schleswig-Holstein, with Lauenburg and Frankfort, were annexed to Prussia; the states north of the Main were formed into the North German confederation under the headship of Prussia. The four South German states, Bavaria, Württemberg, Baden, and Hesse-Darmstadt, were made independent states, but were closely united with the North German confederation by means of the Zollverein and defensive and offensive alliances. Luxemburg and Liechtenstein were dismissed from all connection with the other German states. Thus the term Germany, from 1866 to 1871, designated the North German confederation and the four South German states, with an aggregate area of 204,719 sq. m., and a population in 1867 of 38,581,522. In January, 1871, the North German confederation and the four South German states united to reestablish the German empire, to which, by cession from France, the Reichsland of Alsace-Lorraine was added. This empire is bounded N. by the North sea, Denmark, and the Baltic sea, E. by Russia and Austria, S. by Austria and Switzerland, and W. by France, Belgium, and Holland (including Luxemburg). Its extreme northern point is on the frontier of the province of East Prussia, in lat.  $55^{\circ} 52' N.$ ; its extreme southern point is in the Bavarian district of Swabia and Neuburg, lat.  $47^{\circ} 17'$ . From E. to W. it extends from lon.  $22^{\circ} 52'$ , on the boundary of East Prussia and Russian Poland, to lon.  $5^{\circ} 45'$ , on the line dividing German and French Lorraine. The area is 208,738 sq. m.; pop. in 1871, 41,058,139, or 197 to the square mile.—Stretching from the lofty summit of the Alps to the low beaches of the Baltic, from the picturesque and diversified countries of western Europe to the monotonous plains of the east, Germany encloses a rich variety of mountainous regions, terraced country, table lands, and fertile plains. Though mainly an inland country, it has good outlets to its numerous navigable rivers. Two great river systems, tributary to the North sea and the Black sea, meet in Germany, rendering it the centre of the interior commerce of the European continent. Its climate unites the characteristics of the surrounding countries, holding a mean between the extreme heat of the south and the extreme cold of northern Europe, between the excessive moisture of the western coast countries and the dryness of the eastern plains. Until recently its boundaries were but poorly protected; but the recovery

of Alsace and part of Lorraine, in consequence of the war of 1870-'71, restored to Germany a very strong position for defence, as now the Vosges mountains form the western frontier, and to the former bulwarks against an invader from France, Mentz, Coblenz, Saarlouis, Landau, and Germersheim, a number of equally strong fortresses in Alsace and Lorraine have been added: Metz, Strasburg, Diedenhofen (Thionville), Bitsch, and Neu Breisach. On the south and southeast Germany is protected by the Alpine system and the maze of its projecting spurs, and the mountains separating it from Bohemia. The weakest point of Germany is the E. and N. E. frontier toward Russia. There the Russian territory enters like a wedge into the side of Germany, and the defence of its easternmost provinces depends on its military organization rather than on the three fortresses of Posen, Thorn, and Königsberg.—The vertical configuration of Germany presents three principal groups: the Alpine region south of the Danube, the elevated and terraced central portion, and the level northern country. 1. By the exclusion of Austria from Germany, the Alps have become the southern frontier, and only two comparatively small branches (the Algan Alps between the Rhine and the Lech, and the Bavarian Alps between the Lech and the Salzach) belong to the German empire. 2. The terraced country of central Germany has its nucleus near the junction of the boundaries of Saxony, Bohemia, and Bavaria, about lat.  $50^{\circ}$ , in the Fichtelgebirge, the watershed of the tributaries of the Rhine, Danube, and Elbe. Thence a number of mountain chains of the secondary order radiate in all directions. To the southeast the Bohemian Forest, the frontier between Bavaria and Bohemia, runs nearly 150 m. in parallel rugged chains toward the Danube. Its highest elevation is the Arber, about 4,800 ft. To the northeast the Erzgebirge, the loftiest peaks of which rise to an elevation of 4,000 ft., forms the frontier between Bohemia and Saxony. On the right bank of the Elbe the mountains cluster in a group of sandstone formation (Saxon Switzerland and Lusatia); after which, assuming the name of Sudetic mountains (Riesengebirge, Glatzergebirge), they turn S. E., dividing Bohemia from Silesia, and extending to the head waters of the Oder, where they meet the Carpathians. They culminate in the Schneekoppe, upward of 5,000 ft. high. S. E. of the Fichtelgebirge the Franconian Jura sweeps to the Danube and along its northern bank in a westerly direction into Württemberg, where its long-stretched sharply defined ridges and table lands are known by the names of Raube Alp, Swabian Alp, Aulbuch, &c. In S. W. Germany (grand duchy of Baden), near the head waters of the Danube, the mountain ridge of the Black Forest sets off at a sharp angle from the Swabian Alp in a northerly direction nearly parallel to the Rhine, and skirting the fertile bottom land

of its E. bank. The spurs of this ridge, extending as far N. as the Neckar river, there meet with the Odenwald (grand duchy of Hesse), which, by the Spessart and Rhön (N. W. frontier of Bavaria), and again by the Thuringian and Franconian forests, is connected with the Fichtelgebirge. The territory enclosed by these different ridges, being those sections of Bavaria and Würtemberg N. of the Danube, nearly the whole of Baden, part of the grand duchy of Hesse, and a few of the petty Saxon duchies, is intersected by a number of lesser hill chains. Between this Franconian and Swabian mountain system and the Rhaetian Alps of Austria extends a vast level plain (southern Bavaria), bounded N. by the Danube, W. by the Iller, E. by the Inn and Salzach. The N. W. section of central Germany (always taking the Fichtelgebirge as the centre) appears like a labyrinth of hill chains, few of which attain a considerable elevation. The more important of them are: the Werra mountains, the Habichtswald, the Westerwald, the Taunus (Prussian province of Hesse-Nassau), the Eder hills, Egge hills, Rothhaar hills, and the Haarstrang (Prussian Westphalia). These are all between the Rhine on the west, the Main and Kinzig rivers on the south, the Werra on the east, and the Lippe on the north. The highest summit is the Astenberg in Westphalia, nearly 2,800 ft. high. N. of the Lippe only one other hill chain stretches in a N. W. direction nearly parallel to the Ems, viz., the Teutoburg forest, renowned in German history as the theatre of the conflict by which the rule of the Romans east of the Rhine was broken. E. of the Weser, the Weser hills run parallel to that river, while S. E. of them and N. of the Thuringian system the Hartz appears as an isolated mass of mountains, the highest summit of which (Brocken) reaches the height of 3,737 ft. On the left or western bank of the Rhine the Vosges, extending along the western frontier of Alsace, rise near Colmar to an altitude of about 4,700 ft., and their northern spurs in Rhenish Bavaria and Rhenish Prussia, called the Haardt, the Hunsrück, and the Hochwald, to about 2,700 ft. in the latter range. Further N. the Ardennes send into Rhenish Prussia the ridge of the Eifel (2,500 ft.) and the Hohe Venn. Northeastern offshoots of the Jura cross the southern frontier of Alsace.

3. The great plain of northern Germany extends over the entire breadth of the country N. of a line drawn from the Holland frontier to Osnabrück and Minden, thence E. S. E. to Leipsic, thence S. by E. to a point where the head waters of the Oder and Vistula approach one another. This vast plain, which at some former geological period has undoubtedly formed the bottom of the sea, is traversed only by two ridges of hills, none of which rise above 400 ft. One of these ridges extends from the lower Vistula W. to the Oder above Stettin; the other from Tarnowitz in S. E. Silesia along the Oder to lat. 52° N., then a little to the

north of that parallel through the Prussian provinces of Brandenburg and Saxony into Hanover.—Each of the seas by which Germany is bounded on the north has a peculiar coast configuration. While the coast of the North sea or German ocean is largely indented by deep bays (Dollart and Jahde bays) or wide embouchures (Weser and Elbe), and its “marshes” are the richest and most fertile soil in all Germany, the shores of the Baltic form many extensive lagoons (Haffs), and are generally uninviting and sterile. The advantages which the formation of the shores of the North sea would seem to offer for the development of the maritime interests of Germany, are to a great extent neutralized by the fact that a series of sand banks, called *Watten*, stretch nearly all along the coast. Besides this, the island which commands the entrance of all German ports on the North sea (Helgoland) has been ceded to Great Britain.—Germany is intersected by many rivers. The principal river systems are those of the Danube, Rhine, Weser, Elbe, and Oder. The Danube, flowing from W. to E., has within the empire a length of 400 m. Its principal tributaries in Germany are: on the left or N. bank, the Altmühl, Nab, and Regen; on the right bank, the Iller, Lech, Isar, and Inn. The North sea receives the river systems of the Rhine (469 m. within Germany), the Ems (about 200 m. long), the Weser (400 m. inclusive of the Werra), and the Elbe (500 m. within the empire). The principal tributaries of the Rhine are the Ill, Nahe, and Moselle, on the left bank; the Kinzig, Murg, Neckar, Main, Tauber, Lahn, Sieg, Wipper, Ruhr, and Lippe, on the right. The Weser is formed by the confluence of the Werra and Fulda, and receives only a few tributaries (Werre, Aue, and Hunte on the left, Aller and Leine, Ocker, Wümme, and Geeste on the right). The Elbe has, next to the Danube, the largest river system. Its affluents in the empire are the Mulde, Saale, Jetze, Ilmenau, Schwinge, and Oste, on the left bank; the Black Elster, Havel and Spree, Stecknitz, Elde, and Stör on the right bank. Two thirds of the territory drained by rivers which flow into the Baltic sea belongs to the system of the Oder (about 500 m. within the empire), and its numerous tributaries, the Neisse, Weistritz, Katzbach, Bober, Ucker, and Peene on the left, the Klodnitz, Malapane, Weide, Bartsch, Warthe, Plöne, and Ihna on the right. Of the small river systems the following may be mentioned: the Eider (boundary between Schleswig and Holstein), about 105 m. long; the Pomeranian rivers Rega, Persante, Wipper, Stolpe, Lupow, and Leba; and the Vistula, which in Germany has a length of about 150 m. A number of canals connect several of the large river systems, but only a few of them can compare with the American canals. The most important is the Ludwigs canal, connecting the Danube with the Main (and through this with the Rhine), thus furnishing uninterrupted naviga-

tion from the North to the Black sea. The Rhine and Rhine canal connects the system of these two rivers by joining the Rhine and the Ill. The Brunnerthal canal connects the Ode and Schönlage, tributaries of the Elbe; the Kiel canal connects the North and Baltic seas by the Elbe, and the Streeknitz canal furnishes an outlet from the Elbe into the Baltic by the Trave; by the Finow and Müllrose canal the systems of the Elbe and Oder are connected.—The number of lakes in Germany is large, but most of them are inconsiderable. The following deserve to be mentioned: the lake of Constance (Bodensee), the banks of which belong to five different states, Baden, Württemberg, Bavaria, Austria, and Switzerland; Ammer, Würm, Chiem, and Königs lakes, in Bavaria; Feder lake, Württemberg; lake of Steinhude (*Steinhuder Meer*), in Hanover and Lippe; Zwischenahner Meer, in Oldenburg; lake of Plön, in Holstein; lake of Ratzeburg, in Lauenburg and Mecklenburg; the lakes of Schwerin and Müritz, in Mecklenburg; Schwieloch and Scharnütz lakes, in Brandenburg; Damm and Plön, in Pomerania; Zarnowitz lake, in Pomerania and western Prussia; the Salt lake near Eisleben, in the Prussian province of Saxony; and the lake of Laach, in Rhenish Prussia.—The climate of Germany is temperate, and, considering the extent of the country, remarkably uniform, the greater heat of the lower latitudes being tempered by the greater elevation of the country and its Alpine character. On the great plain of northern Germany the districts exposed to the moist west and southwest winds have a more inclement climate than central Germany; while the southernmost districts, though drier, have less heat than more northern latitudes. The average decrease of the mean temperature, going from S. to N., is 1° F. in 52 m., and going from W. to E. 1° in 72 m.; measured by the vertical elevation, it is 1° in 256 ft. The mean annual temperature of Stralsund (lat. 54° 18' N., lon. 13° 5' 23" E.) is 46.4°; the mean temperature in summer 63°, in winter 29.8°. The mean annual temperature of the valley of the Rhine is 52°, of Thuringia 47.5°, of Silesia 47°, of all Germany 48.8°. The extremes of temperature in the country N. of the Alps are 95° above and 31° below zero. In an average of 10 years the Rhine had been frozen over 26 days during each winter, the Weser 30 days, the Elbe 62 days, the Oder 70 days. The atmosphere is pure and wholesome, and unfavorable to the development of endemic or hereditary diseases, except in the high Alpine valleys, where cretinism prevails. Epidemics are generally less destructive in Germany than in the neighboring countries.—Of wild animals, the deer, hare, rabbit, fox, hamster (a kind of marmot peculiar to Germany), marten, badger, weasel, otter (rare), &c., are found nearly everywhere, stringent game laws preventing their destruction. A good breed of horses

is raised in Mecklenburg, Holstein, and Hannover; cattle raising is a most important branch of husbandry in Oldenburg, the N. W. part of Hanover, Franconia, and the Alpine country. sheep are raised extensively in Saxony, Silesia, and Brandenburg; Saxony furnishes the best quality of wool; goats, mules, and asses are reared principally in the mountainous districts of the south; hogs in all states, but chiefly in the west. Large birds of prey (the eagle and vulture) are rarely found beyond the Alpine districts; fowl of all kinds, wild and domestic, are plentiful in all parts of the country. Germany has only a few species of amphibians; there are only two venomous kinds of snakes, *Vipera berus* and *V. chersea*. Carp and pike are numerous in nearly all rivers and ponds, the salmon only in the larger rivers; sturgeon, cod, and sheatfish in the Elbe, trout in all mountain streams; herring and sardines in the Baltic and North sea. Oysters of good quality are obtained near the shores of Schleswig-Holstein, and pearl mussels in some rivers of the interior. The silkworm is not raised extensively.—Germany is rich in mineral products, and mining has employed there a great number of persons from the remotest times. Gold is found only in a few places in limited quantities (in the Hartz mountains and in the kingdom of Saxony); silver abounds in the Hartz and in southern Westphalia; iron is found in large quantities in nearly all the mountain ranges, the best qualities being those worked in Westphalia, Alsace-Lorraine, and Rhenish Prussia; excellent tin abounds in the Erzgebirge; lead in Saxony and upper Silesia; calamine and zinc in Silesia; cobalt in Saxony. Salt is obtained in quantities more than sufficient for domestic consumption in all the states except Saxony and Anhalt. The production of coal has been enormously increased within the last 40 years. The most extensive coal beds occur in Rhenish Prussia, Westphalia, upper Silesia, Saxony, and Anhalt. The N. W. districts have instead an abundant supply of peat. Sulphur, saltpetre, alum, vitriol, gypsum, chalk, ochre, emery, porcelain clay, graphite, marble, alabaster, and amber (on the shores of the Baltic) are found in different districts. Precious stones are comparatively scarce. Of mineral springs Germany has a great number, and several of them (Pyrmont, Ems, Wiesbaden, Selzter, Homburg, Baden-Baden, Kissingen, Schwalbach, Salzbrunn, Warmbrunn, &c.) enjoy a world-wide reputation.—The soil on the whole is only of moderate fertility. Many tracts are exuberantly productive, but many others are almost as barren and sterile as the Russian steppes. The most fertile tracts of land in Germany and in Europe are the marshes on the shore of the North sea. Scientific agriculture has improved the natural condition of the soil in a high degree. All kinds of grain and fruit belonging to the temperate zone are raised: rye, barley, oats, potatoes, peas, and beans, everywhere;

maize principally in the south; wheat in the south and west; buckwheat in the north; millet in the southeast; rapeseed, poppy, anise, and cumin in the central and northwest districts. The largest grain fields are in Württemberg, the smallest in Mecklenburg. Bavaria, Württemberg, Saxe-Altenburg, Mecklenburg, Holstein, &c., produce a larger quantity of breadstuffs than is required for home consumption, while Saxony and some of the Saxon duchies import breadstuffs. Flax and hemp, madder, woad, and saffron are cultivated more in the south and central region than in the north. Tobacco is extensively raised (even for exportation to other tobacco-growing countries) on the upper Rhine, the Werra and Oder, and in Brandenburg. Excellent hops are furnished by Bavaria and Brunswick. Beets are raised in enormous quantities for the manufacture of sugar, and their cultivation has almost entirely superseded the grain culture in the Prussian province of Saxony, Anhalt, Hesse-Darmstadt, and S. Bavaria. Chicory, as a substitute for coffee, is raised in the country between the Elbe and Weser rivers. In garden culture Württemberg, Bavaria, Hesse, and the Saxon duchies hold the highest rank. The fruit raised on the banks of the Rhine and Neckar, in Saxony and N. W. Bavaria, is of the very best quality to be found anywhere. Peaches and figs ripen only in localities protected from the cold. The apples of Saxony are of the choicest kind, and are exported to Russia in large quantities. Marron chestnuts, almonds, &c., are raised in the S. W. states. Great attention is paid to the improvement of fruit. In all the states there are pomological societies, which from time to time hold national conventions. The culture of the vine extends to lat.  $51^{\circ} 30'$ . (See GERMANY, WINES OF.)—The three free cities excepted, the greatest density of population prevails in the principality of Reuss elder line (473 to the square mile), the kingdom of Saxony (442), the grand duchy of Hesse (288), and the duchy of Saxe-Altenburg (256). In the following states it exceeds the average: Württemberg, Baden, Brunswick, Saxe-Coburg-Gotha, Schwarzburg, Reuss younger line, Lippe, Anhalt, and Saxe-Weimar. In Prussia it is 184, in Bavaria 166. The number of large cities, proportionately to the population, is greater in Germany than in any other country except Great Britain, Belgium, and Holland. There is one city with more than 800,000 inhabitants (Berlin), two with more than 200,000 (Hamburg and Breslau), seven with more than 100,000 (Dresden, Munich, Cologne, Magdeburg, Königsberg, Leipzig, and Hanover), 22 with more than 50,000, and 50 with from 20,000 to 50,000. More than nine tenths (92 per cent.) of the population of Germany belong to the German race; the remainder, belonging principally to the Slavic race, is mainly confined to the eastern Prussian provinces. The entire number of Slavs in Germany is about 2,640,000 (2,450,000

Poles, 140,000 Wends, 50,000 Czechs), or 64 per cent., of which number only about 50,000 are outside of Prussia. In the latter country there are also about 150,000 Lithuanians and Letts. The Danes, in Schleswig, number about 150,000, and the French, chiefly in Lorraine, 280,000. Except Ireland, no country of Europe has lost so large a number of inhabitants by emigration as Germany. From 1819 to 1855 the aggregate number of German emigrants was estimated at 1,800,000. The number of German immigrants into the United States from 1820 to 1872 amounted to 2,580,000. The Germans are usually classified into Low Germans and High Germans, or northerners and southerners. The dividing line may be drawn from lat.  $50^{\circ} 30'$  in western Germany to lat.  $52^{\circ} 30'$  on the eastern frontier, or along the course of the Sieg (a tributary of the Rhine) to the southern slope of the Hartz mountains, crossing the Elbe near its confluence with the Saale, then a little to the northward along the southern banks of the Havel and of the Warthe. In physical development the Germans are superior to either the Latin or the Slavic race. Their frame and their muscular development are strong, almost heavy. Among the lower classes of the rural and laboring population stoutness and strength often approach to clumsiness. Generally the northerners are taller and have better-shaped features and limbs than the southerners. The blonde complexion prevails only in the north; in central and southern Germany light or dark brown is more frequently found. In power of endurance the Germans are surpassed by the Slavic race, in agility by the Latin. The prominent features of the German national character are honesty, faithfulness, valor, thoughtfulness, perseverance, and industry. The Germans have largely promoted the progress of human knowledge. There is scarcely a single branch of science in which they have not excelled. In music, painting, and sculpture they occupy a very high rank among nations. The German artisan is valued for his dexterity and steadiness. The sectional and local diversities of character are very great in Germany. While the Protestant northerners have many characteristics in common with the Anglo-Saxon, the Catholic southerners approach in some important respects the Latin race, particularly in a certain preponderance of imagination over reason. The Low German assimilates far more readily to the English or American than to the Austrian or Swabian.—The culture of the soil in Germany is highly developed, and inferior only to that of England. The products of agriculture have been nearly doubled by the introduction of more rational methods of cultivation since 1816. All German states have agricultural colleges, some of which enjoy a world-wide reputation. The methods of cultivation are different in different portions of the country. The triennial and quadrennial rotations of crops are most in use. According to the first method,

*kapála*, Gr. *κεφαλή*, Lat. *caput*, Goth. *haubith*, O. H. Ger. *houpit*, Ger. *Haupt*, Eng. *head*. 8. Sansk. *trayas* (nom. pl.), Gr. *τρεῖς*, Lat. *tres*, Goth. *threis*, O. H. Ger. *drī*, Ger. *drei*, Eng. *three*. 9. Sansk. *pañcan*, Gr. *πέντε*, Goth. *finf*, Eng. *five*. Sansk. *upari*, Gr. *ὑπέρ*, Lat. *super*, Goth. *ufar*, O. H. Ger. *ubar*, Ger. *über*, Eng. *over*.—For further information see the articles on the principal languages and dialects. **GERMANICUS CÆSAR**, a Roman general, born in Rome, 15 B. C., died near Antioch in A. D. 19. He was the son of Claudius Nero Drusus and Antonia, the daughter of the triumvir Antony, and was adopted by his uncle Tiberius in accordance with the will of Augustus. His original names are unknown. In 7 he accompanied Tiberius against the rebels of Dalmatia, served with distinction during three campaigns, and on his return to Rome received a triumph and the hand of Agrippina, granddaughter of Augustus. At the close of another campaign, in 11, he was made consul, and in the following year was placed in command of the eight legions on the Rhine. He was absent in Gaul when upon the death of Augustus (14) a universal sedition broke out in the army. He was a favorite with the soldiers, and they had already determined to raise him to the head of the empire, when he suddenly returned to the camp, and at the peril of his life succeeded in repressing two successive revolts, and in establishing Tiberius upon the throne. He immediately marched the pacified legions against the enemy across the Rhine, and routed the Marsi, whom he fell upon by night as they were celebrating a festival. Being soon after appointed commander-in-chief of all the legions of Germany, he began that series of exploits which gained him

his title of Germanicus. He marched against the native hero Arminius, the conqueror of Varus, defeated him, and made his wife Thusnelda prisoner; then penetrated to the Teutoburg forest, near the sources of the Lippe, the scene of Varus's disaster, and buried the bones of the legionaries who had fallen there. Yet Arminius hovered about the Roman army in impracticable places, attacked it in a narrow pass, and drove it into a marsh with so great loss that Germanicus decided to retreat to the Rhine. In the year 16 he returned against the Germans with a fleet of 1,000 vessels, landed at the mouth of the Ems, crossed the Ems and the Weser, and defeated Arminius first on the plains of Idistavisus and then in the vicinity of Minden. He determined thereupon to return, but he lost a part of his fleet in a storm, and his own vessel stranded on the shores of the Chauci. Fearing that his losses might embolden the Germans, he sent Silius against the Catti, while he himself attacked the Marsi. He purposed to pursue his advantages in the following year, when Tiberius, jealous of his fame, recalled him, and in the triumph which was granted him Thusnelda figured among the captives. To rid himself of Germanicus the emperor sent him to the East to fight the Parthians and to pacify Armenia. He at the same time gave the government of Syria to Lucius Piso, with secret instructions to thwart and annoy Germanicus. The latter hastened to Armenia, and placed the crown upon Zeno. He subsequently reduced Cappadocia to a province, and gave the command of Commagene to Servæus. At the request of Artabanus, king of the Parthians, he removed Vonones, the deposed monarch, to Pompeiopolis. In the year 19 he visited Egypt without the special permission of the emperor, as required at the time. On his return to Syria he suddenly fell ill and Agrippina brought his ashes to Italy amid universal mourning; honors almost unknown in Roman history were paid to his memory, and Piso, accused by the senate of having poisoned him, anticipated his condemnation by a voluntary death. Germanicus is the "Annals" of Tacitus, and is one of the noblest characters in the history of the empire. He had reputation as a philosopher and poet, but of several works which he composed there remains only a small fragment of the *Phænomena* of Aratus, which he translated to Cicero's translation of the same work. He was the father of the emperor Nero.

**GERMAN IVY** (*senecio scandens*), a climbing plant, cultivated for its quick-growing habit, but which is not properly called ivy, as it is one of the composite family, and not the Cape of Good Hope. Its leaves are ovate to the height of 8 or 10 ft., and are marked with round heart-shaped spots, and several pointed lobes, of a light green color, and a light green color when seen in bloom, but it is not in flower. It forms bell-like clusters of

It grows readily from cuttings, flourishes well in the dry atmosphere of dwelling rooms, and is admirably adapted to window culture; in the

German Ivy.

open ground it is a useful climber where it is desired to cover a surface quickly, but it is killed by the first frost.

**GERMAN OCEAN.** See NORTH SEA.

**GERMAN SILVER**, or *Argentane*, an alloy resembling silver, made of variable proportions of its ingredients according to the uses for which it is designed. A composition of 8 parts of copper to 3 each of nickel and zinc is recommended as making a close imitation of silver of 75%. The two latter metals are also used in the proportions of 4 each to 8 of copper. By using a larger proportion of copper the alloy is more easily rolled into plates, but the copper sooner becomes apparent in use. Iron used in the proportion of 2 to 2½ per cent. renders the composition whiter but more brittle. The genuine German silver, made from the original ore of Hildburghausen in Henneberg, analyzed by Keferstein, was found to consist of copper 40.4 per cent., nickel 31.6, zinc 25.4, iron 2.6.

**GERMANTOWN**, formerly a post borough of Philadelphia co., Pennsylvania, 6 m. N. W. of the state house, Philadelphia, and included since 1854 in the 22d ward of that city; pop. of the ward in 1870, 22,605. It has one main street, about 4 m. long, extending S. S. E. and N. N. W., which is intersected at right angles by several others. It is lighted with gas, is well supplied with water, and is connected with Philadelphia by both a steam and a horse railway. Many retired merchants and wealthy citizens of Philadelphia have here their residences, some of which are of great elegance. Among the public buildings are 21 churches, an academy and other schools, and a bank. There are also a number of extensive manufactories.—Germantown was laid out in 1684 under a grant from William Penn, and settled by

Germana, whence its name. It is memorable as the scene of the defeat of the American army under Washington by the British on Oct. 4, 1777. Washington, having learned that Gen. Howe had detached a portion of the main division of his army, then at Germantown, determined to take advantage of it to attack his camp. After marching all night, he entered the town about sunrise. The enemy, who were encamped across the main street at right angles, were taken by surprise, but the morning being dark and foggy, the Americans were thrown into confusion by the many small enclosures of the village, and the British rallied and attacked in turn. Some of the Americans were seized with a panic, and what had promised to be a victory was changed into a defeat. Washington withdrew in good order, with all his artillery. The British loss was upward of 600; the American about 1,000.

**GERMANUS** (Fr. St. GERMAIN L'AUXERROIS), a saint of the Roman Catholic church, born in Auxerre, central Gaul, about 380, died in Ravenna, July 31, 448 or 449. He was of a senatorial family, studied literature and jurisprudence, and distinguished himself for eloquence. He was made by the emperor Honorius military governor of his native district, and in 418 was elected bishop of Auxerre, although a married man. He separated from his wife, gave his property to the poor, and built a monastery on the river Yonne. He twice visited England at the request of Celestine I., and by his authority the doctrines of Pelagius were condemned and suppressed there, and schools for the education of the clergy were opened. He once led the Britons against a party of Picts and Saxons who were plundering the coast, and terrified them into retreat by a general shout of "Hallelujah," an action known under the name of the Hallelujah victory. He encouraged St. Patrick to undertake the conversion of the Irish, and in 447 went to Ravenna to mediate between the revolted Bretons and Valentinian III. His feast is celebrated on July 31. A manuscript preserved in the abbey of St. Gall, entitled *Liber Sancti Ambrosii in Laudem Sanctorum compositus*, is said by the Benedictine editors of St. Ambrose to have been probably written by St. Germanus. His life, written 30 years after his death by the priest Constantius, and put in verse by the monk Eric, is to be found in Labbe's *Nova Bibliotheca Manuscriptorum*. A new life of St. Germanus was given in vols. ix. and xi. of Newman's "Lives of the English Saints" (London, 1844).

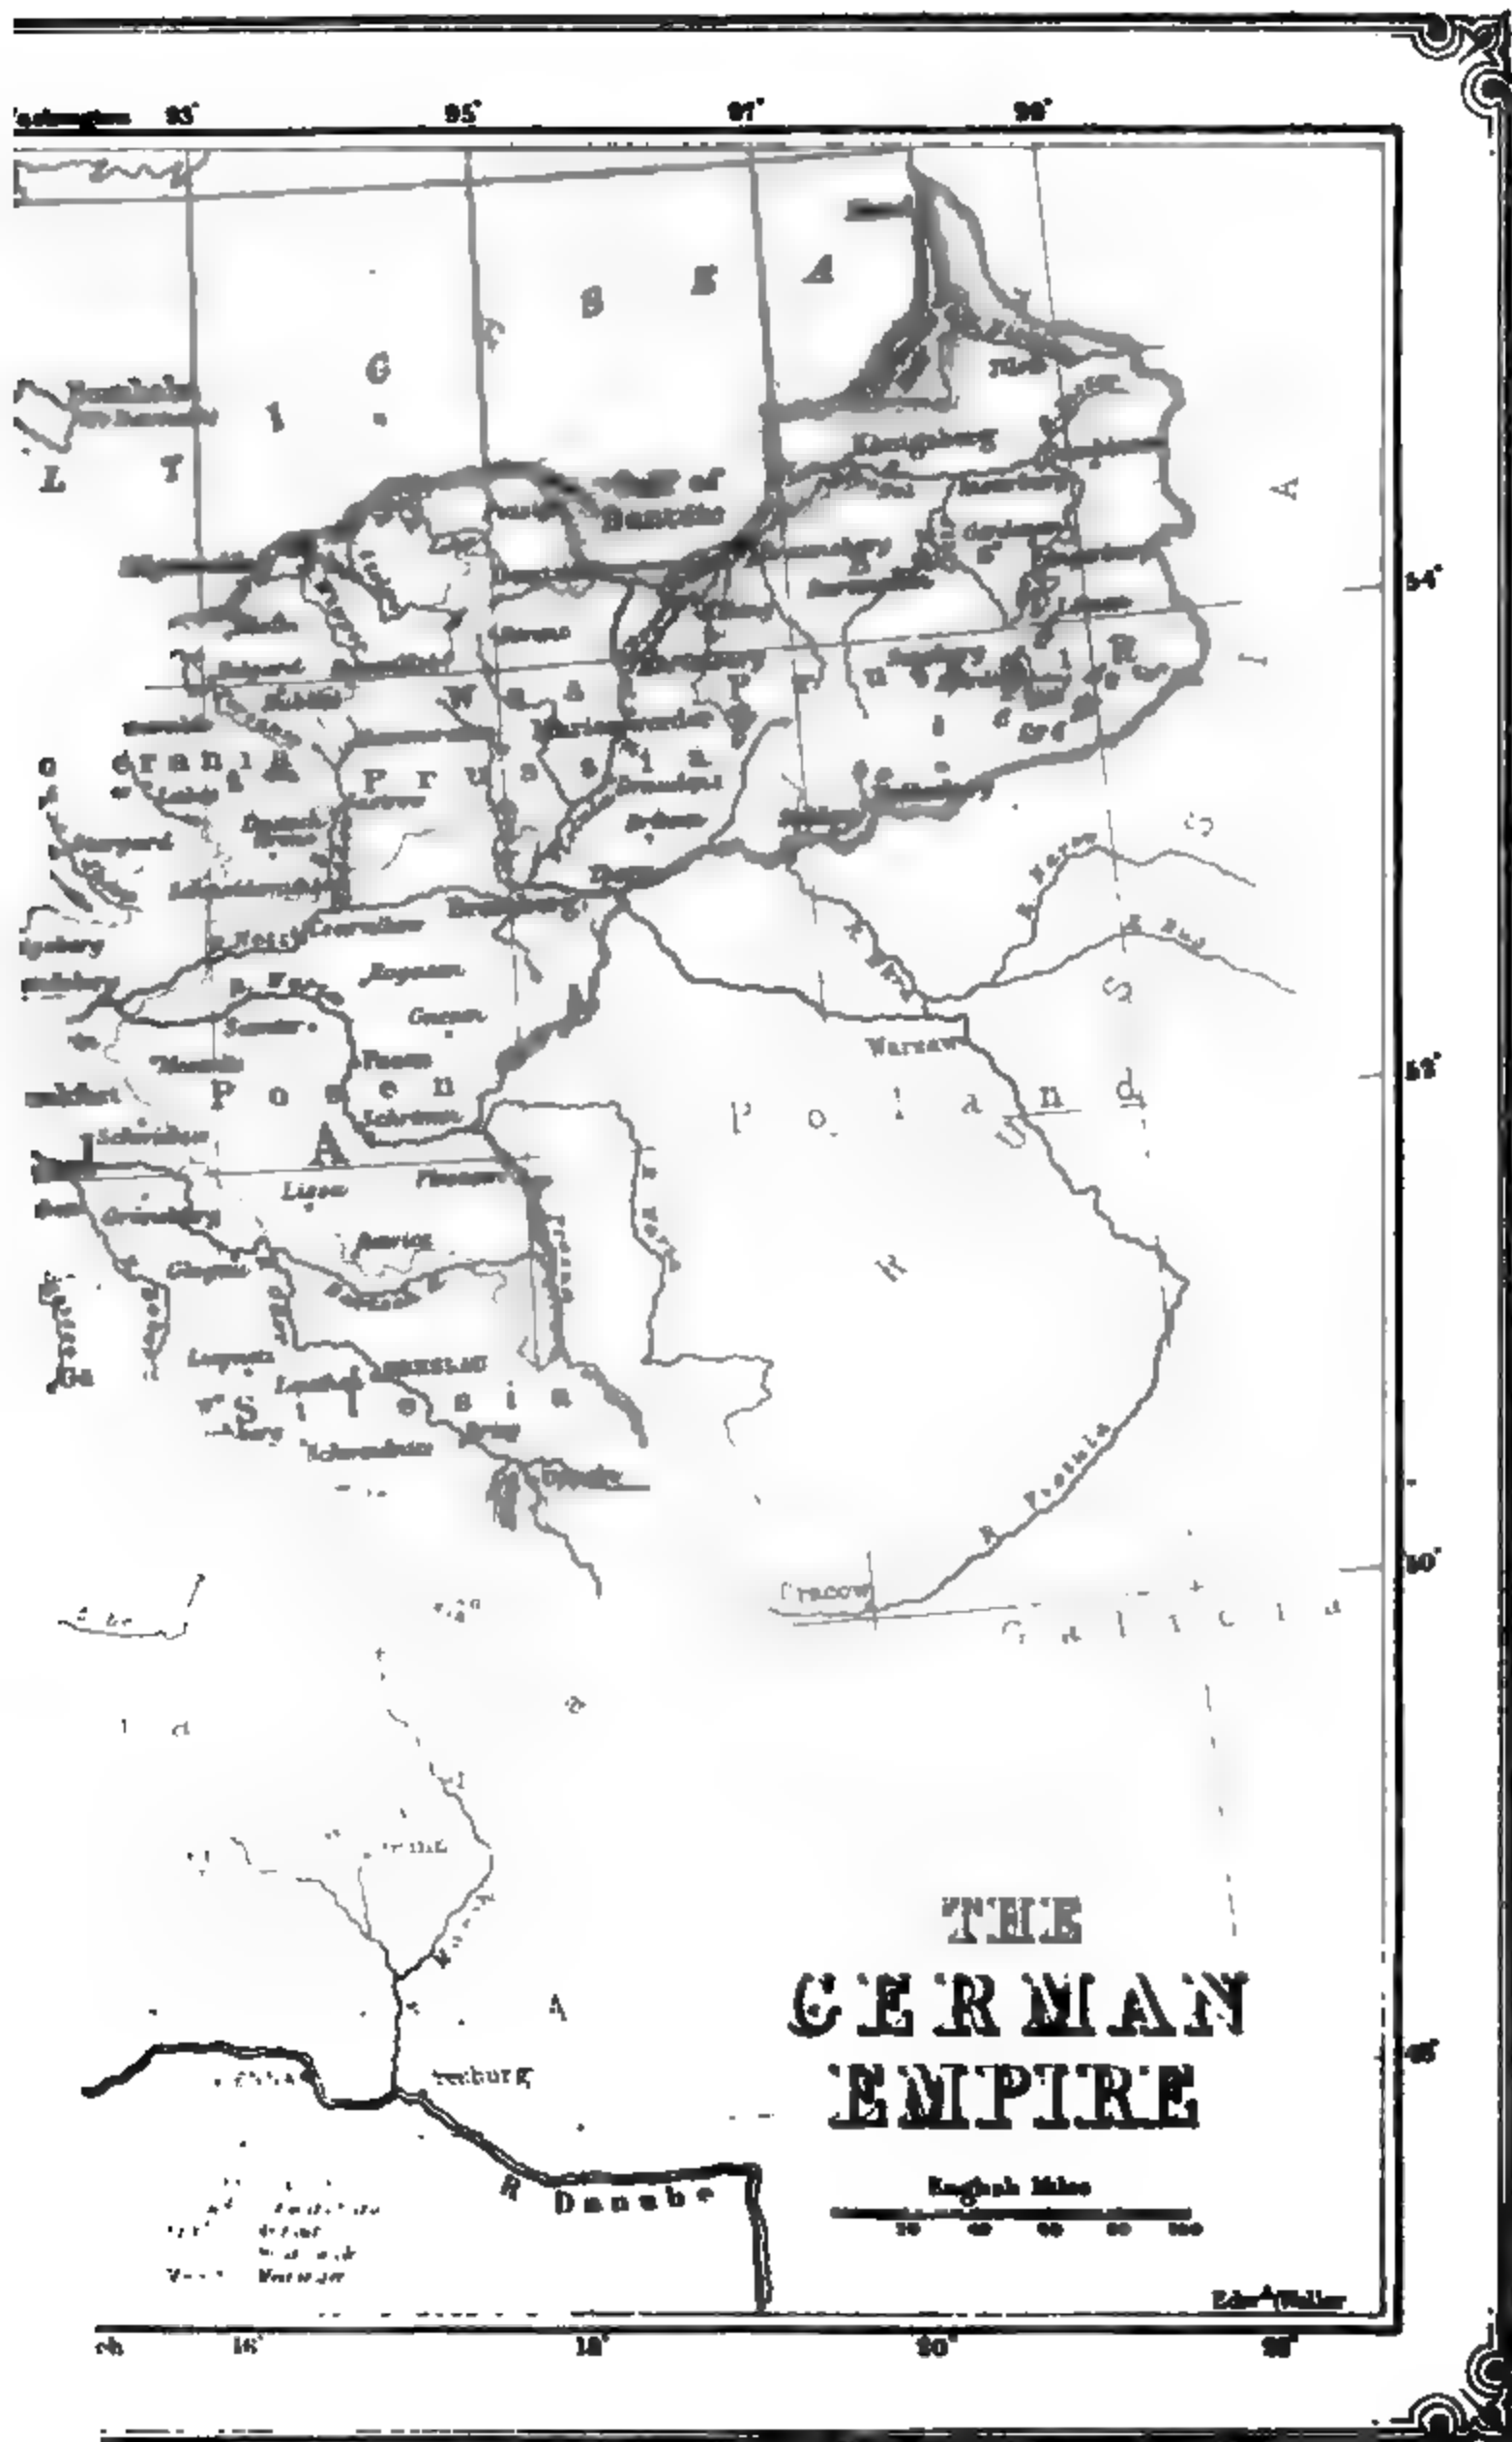

**GERMANY** (Ger. *Deutschland*; Fr. *Allemagne*), formerly a large empire of central Europe, with an area at the time of the first French revolution of 287,714 sq. m., and 26,265,000 inhabitants. From 1806 to 1815 it was dismembered and disorganized. In 1815 the German confederation (*Deutscher Bund*) was established in the place of the old German empire, embracing part of Austria (the present

Toul, Metz, and Verdun had been wrested from the German empire by France. Disgusted with the successes of his adversaries, Charles resigned the crown. He was succeeded by his brother Ferdinand I. (1556-'64). The imperial authority was rapidly sinking to utter insignificance. France in the west and Turkey in the east were hovering on the borders of Germany, ready on every occasion to foster the internal dissensions of the empire and to conquer from it valuable possessions. The feeble Maximilian II. (1564-'76), the visionary Rudolph II. (1576-1612), and his brother Matthias (1612-'19), were unable to arrest the political decay. The thirty years' war (1618-'48), which devastated and impoverished Germany, destroying all industry and commerce, left the imperial authority completely shattered, and Germany cut up into a multitude of petty states, whose rulers were absolute monarchs in fact, if not in name. The persecutions perpetrated by Ferdinand II. (1619-'37) on his Protestant subjects almost equalled those of Philip II. of Spain. The peace of Westphalia (1648), concluded by Ferdinand III. (1637-'57), tore Alsace from the German empire. Under the pedantic and feeble-minded Leopold I. (1658-1705) Germany took part in the coalition against the rising power of France, but, although successful in war, did not obtain any signal advantages by the peace. From that time the title of German emperor appeared only as an empty surname of the rulers of Austria (Joseph I., Charles VI., Francis I., the husband of Maria Theresa, whose enemy, Charles Albert of Bavaria, was also crowned as Charles VII., &c.). In fact, Germany was merely a maze of little despotisms, among which a few larger states were endeavoring to obtain a voice in the councils of Europe. Prussia (a kingdom since 1701), through the genius of Frederick the Great, established a great Protestant power, able to cope with Austria, but at the same time anxious to prevent the reconstruction of a great united empire. Thus the attempts of the emperor Joseph II. (1765-'90, or rather 1780-'90, when he reigned himself) to reestablish the imperial authority in southern Germany were baffled by Prussia. At last the tempest of the French revolution prostrated the tottering fabric of the German empire. Vanquished by the armies of France, the emperor Francis II., son and successor (1792) of Leopold II., ceded by the treaties of Campo Formio (1797) and Lunéville (1801) the country on the left bank of the Rhine. The petty rulers who lost their possessions in this way were indemnified with the territories of ecclesiastical princes. In 1805 several states seceded from the empire and became allies of France; and when at last, in 1806, a number of German states formed the Rhenish confederation under the protectorate of Napoleon, the emperor Francis resigned the German crown, and the empire was formally dissolved. A number of the smaller territories

were annexed to the larger states, and most of the free cities, which while under the nominal authority of the emperors had enjoyed a sort of republican government, lost their independence. The efforts of Prussia to oppose to this confederation a North German league having been frustrated, nearly the whole of Germany, with the exception of Austria and Prussia, was reduced to a state of French vassalage. The minions of the emperor Napoleon ruled the country with an iron rod, and if they removed many of the most glaring remnants of feudal despotism, they introduced in their stead all the abuses of an irresponsible military regime, and carried their extortions to a frightful extent. The sums drawn from Germany by Napoleon under the designation of contributions or subsidies must be counted by hundreds of millions. The independence of the country was reestablished by the coalition of Austria, Russia, Prussia, Sweden, and Great Britain (1813-'15). A reconstruction of the old empire having been rendered impossible by the position which Prussia had assumed, a confederation was formed by all those states which had contrived to maintain their sovereignty during the Napoleonic troubles (June 8, 1815). This number, which had exceeded 300 at the time of the dissolution of the empire, had then been reduced to less than 40, and a further reduction was made afterward by the extinction of several petty dynasties. The enthusiastic of the German people that Germany more appear as a powerful united, sorely disappointed. The diet, a permanent convention of the republican princes, all jealous of their individual liberty and unwilling to recognize the confederation, became an abject tool of oppression, and a harmonious co-existence of states existed only in name. Measures against all progress, ever the people of Germany to obtain free institutions, to interfere in favor of despotic power. None of the promises of an act of confederation in regard to legislation, a common currency, and other matters, &c., were fulfilled. Whatever in this respect was due to the states. Thus the Prussian Zollverein, a large portion of the confederation, consisting of commercial states, made a great advance, and kept alive the idea of a national union. In the south, however, found an echo in some of the states, whose rulers were opposed to written constitutions, and to a more vigorous political life. In the southwestern states, under the influence of the Prussian throne of Frederick William (1840), in northern Germany, the people became more active, while in Austria all progress was suppressed by the despotic

ternich. Immediately on the downfall of the Orleans dynasty in France (Feb. 24, 1848), insurrections broke out in all the German states. The princes, unable to resist these movements, hastened to yield to the popular demands. A national congress of representatives of the people (German parliament) was convoked by a provisional self-constituted assembly (*Vorparlament*), and met at Frankfort, May 18, 1848. It formed a provisional national government, consisting of a vicar of the empire (*Reichsverweser*) and a ministry. Archduke John of Austria was elected vicar, June 29; but in spite of his professions of zeal for national liberty and union, it soon became evident that his principal aim was the frustration of all energetic action on the part of the parliament. Distracted by the troubles in Holstein, which Denmark endeavored to wrest entirely from its connection with the German confederation, the parliament made but slow progress in framing a national constitution. When at last the bill of rights had been agreed upon (December, 1848), the counter-revolution had already been victorious in Austria and Prussia, and it became apparent that these great powers would not submit to a constitution framed by the popular congress. Then a strong party began to advocate the exclusion of Austria from the new empire. This party, whose principal leader was Gagern, prevailed in the parliament, and elected the king of Prussia German emperor (March 28, 1849); but he declined the honor. Despairing of success, a number of members of parliament resigned their position, thus giving a majority to the democratic party, who elected a provisional regency of the empire, consisting of Raveaux, Vogt, Schüler, H. Simon, and Becher. Reduced to less than one third of its original number, the parliament adjourned to Stuttgart, May 30, 1849, and endeavored to raise a popular revolution in favor of the new national constitution. But only the people of Baden, a small part of Würtemberg, and the Palatinate (Bavaria) followed the example of Saxony, which had already risen in revolution. The insurrection at Dresden had been suppressed after a sanguinary battle by Prussian soldiery; and the revolution in Baden, although successful for a few weeks, was likewise crushed in a brief campaign by the Prussian army (June). The rump parliament of Stuttgart had in the mean time been forcibly dissolved by the government of Würtemberg. Having thus got rid of all revolutionary support, the Prussian government attempted to obtain the mastership of Germany on its own account. Austria, almost prostrated at the time by the Hungarian war, would have been able to offer little or no resistance to such a movement if carried on energetically and rapidly; but the Prussian government was no match for the bold and shrewd Prince Schwarzenberg, at that time the soul of the Austrian government. In March, 1850, Prussia assembled at Erfurt a new parliament of representatives

of those petty states which were too powerless to resist its demands, and a sort of federal constitution was adopted by it, but never obtained any real existence. To cut short all further attempts of Prussia, Austria convoked the old diet, which had been formally dissolved in 1848. Prussia refusing to recognize the diet, a hostile conflict between Austria and Prussia seemed almost inevitable. The armies of both were marching to Hesse-Cassel, and a skirmish of the outposts had taken place near Bronzell (Nov. 8, 1850), when suddenly the Prussian government lost courage and submitted to all the demands of Austria. The first fruits of the restoration of the diet were the intervention in Schleswig-Holstein in favor of Denmark, the abolition of the national bill of rights and of free constitutions in several of the smaller states, and the sale by auction of the national navy which had been created by voluntary contributions of the people during the revolution. While in these questions the influence of Austria prevailed, Prussia balanced its loss of political power by the enlargement of its commercial influence. Hanover became a member of the Zollverein (September, 1851), and was soon followed by Oldenburg and Schaumburg-Lippe. The efforts of Austria to enter the Zollverein, in order to destroy the Prussian influence even there, were successfully resisted by Prussia, but a postal and telegraph union of all German states was accomplished. During the eastern war (1853-'6) the German confederation followed a vacillating policy, swaying to and fro between Austria and Prussia. In April, 1854, those two powers concluded a treaty of alliance, guaranteeing to each other their respective possessions against all enemies whatever. The diet joined in this treaty July 24, and in December added another clause, promising the assistance of all Germany to Austria if its army of occupation in the Danubian principalities should be attacked. Preparation for war was resolved upon by the diet, Feb. 8, 1855. After that the position of Prussia toward Austria became more reserved, and Austria, despairing of active assistance on the part of the confederation, was compelled to relinquish its intention to take part in the war against Russia. In November, 1856, the diet adopted a resolution promising to assist Prussia in its attempts to reconquer Neufchâtel, but the proffered assistance was not required. In 1857 the interference of the diet was requested against the attempts of Denmark to merge the duchies of Holstein and Lauenburg completely in the Danish kingdom. After long hesitation and delay a resolution was adopted in 1858, by which the Danish government was compelled to submit its project of a new political organization to the legislative assemblies of the duchies. When, in the beginning of 1859, difficulties arose between France and Austria on account of the state of Italy, a violent anti-Napoleonic feeling

manifested itself in Germany. The Prussian government, though willing to defend Austria's German provinces, and even the Lombardo-Venetian kingdom, under certain restrictions, would not stir unless it should obtain the military leadership of all Germany, irrespective of all limitations contained in the act of confederation. After long and angry discussions the leadership was conceded to Prussia by the smaller states. A circular despatch of the Russian government, covertly threatening Germany if it should interfere in the Italian war, had no effect but the assumption by Prussia of a more defiant attitude toward France, and the issue of an order by the prince regent to mobilize two thirds of the Prussian army (June, 1859). A few days later, the Prussian delegate in the diet moved that two federal army corps under the command of Bavaria be stationed on the upper Rhine, and one Prussian corps on the Main, and that the 9th and 10th federal army corps be united with the Prussian army. This motion was followed by another, to the effect that the diet should appoint a commander-in-chief of the non-Prussian and non-Austrian army corps. Thus the German confederation appeared to be on the very point of waging war against France, under Prussian leadership, when all at once Austria, unwilling to sacrifice its preponderating influence in Germany to the doubtful project of preserving its Italian provinces, introduced in the diet a resolution to mobilize the whole federal army, and to appoint the Prussian prince regent commander-in-chief, subject to the control of the diet, or rather of Austria, the latter being always certain of a majority in the diet. This movement at once neutralized all advantages Prussia had obtained. And when the preliminaries of peace were agreed upon by the emperors of France and Austria at Villafranca, July 11, the dissension and jealousy between Austria and Prussia, those great impediments to German unity, were more apparent than ever before. A passage in the Austrian emperor's proclamation of peace, in which he asserted that his natural allies had forsaken him, and that the neutral powers would have imposed upon him less favorable terms of peace than were offered by his adversary, gave rise to an acrimonious correspondence between the Austrian and Prussian governments. The latter succeeded in proving that the assertion of the emperor had no foundation in fact, and that he had been purposely misled by false representations of the French ruler at the interview of Villafranca. This singular discovery did not render the feeling of Austria any more friendly toward Prussia. A paper war was carried on by the presses of southern and northern Germany, and while the governments of those petty states who had been the most forward in their hostile demonstrations against France were eagerly courting the favor of Napoleon III., the most sinister threats against Prussia came from Vienna, Munich, and

Carlsruhe. The opinion became prevalent that Austria having been humbled by France in a war for the conquest of the left bank of the Rhine should be waged by France against Prussia, the latter would not obtain any assistance either from Austria or the smaller German states. The hostility of the two great sections of Germany manifested itself in sanguinary riots in the mixed Prussian and Austrian garrison of the federal capital (Aug. 6-8). Feeble movements were initiated by the liberal party to arrest the progress of disunion, and to prompt the Prussian government to take the lead in reforming the federal constitution. But Prussia, disheartened and unwilling openly to oppose the influence of Austria, declined the destiny which the liberal party pressed upon it, and would promise nothing more than the promotion of liberal institutions by the power of its example. Austria, on the other hand, made some show of concessions to the wishes, in order to divide the current sympathies of the popular party in Germany. A committee was appointed by the emperor (August) to draw up a constitution on the basis of provincial representation for the Austrian empire. At the same time a movement was initiated in Prussia, of which was the creation of a new confederation of the central German states, a third great power within Germany. This idea had been promoted by Bavaria, and then led to confusion and disunion. Withstanding the discouraging example of the Prussian government, the liberal party in many on Sept. 16 established a new confederation, the *Nationalverein*. In a meeting in all the particular states of the confederation (Sept. 16-17) a compact federal state was proposed (the *Bundesstaat*), under which Prussia. Prussia in no way expressed its opposition to this project, but it was not to be opposed in the federal diet by Prussia and its allies. It moved for the federal constitution of Hesse-Cassel, which in 1852 had been abolished in an illegal way, be restored. The diet of Hesse-Cassel fully approved the project, but in the federal diet the project led to its rejection. In the diet of Prussia for a reform of the constitution of the confederation was likewise rejected. The attitude of Austria toward the central and federal government was what mitigated by the fundamental law in Austria which appeared as a constitutional principle. Prussia greatly offended the conservative principles of William I., who on Jan. 18, 1861, his brother Frederick William IV. the Saxon minister von Arnim, ardent champions of

presented to Prussia a new project of the federal constitution, according to which a representation of the German nation at the federal diet was to be created by the establishment of an assembly of delegates chosen by the diets of the several states. Austria declared its readiness to accept this project, which gave to Austria and Prussia an equal number of delegates, if she should be allowed to enter the confederation with her entire territory. Prussia in a note of Dec. 20 declared it to be impracticable, and instead advocated the establishment of a federal state, on the plan which had been tried ten years before. This idea was promptly rejected by all the middle states in February, 1862, on the ground that it would involve the loss of their sovereignty. In August they united with Austria in submitting another plan of reform, according to which an assembly of delegates of the several German diets was to be convoked at Frankfort for the special purpose of deliberating on some reforms in the civil and commercial legislation of the German states. An assembly of liberal German deputies, held in September at Weimar, declared against this plan as wholly unsatisfactory, while on the other hand it was approved by the new national reform association (*Reformverein*), which in October was organized at Frankfort as the organ of those who unconditionally opposed the exclusion of Austria from Germany and the establishment of a Prussian leadership. In the federal diet, in January, 1863, it was defeated by a small majority. In the mean while the incessant conflicts between the Prussian liberals and their ultra-reactionary government had led, in September, to the entrance into the ministry of Otto von Bismarck, who soon after became its president and minister of foreign affairs. The uncompromising firmness with which he opposed the views of the Prussian diet on a reduction of the military budget filled even the Prussian friends of national unity with despair. Little was known of the ultimate plans of Bismarck with regard to German unity; but it was apparent that Prussia desired to be emancipated from the federal diet, and that her plans would henceforth be pushed with greater energy than at any previous time. The union movement was steadily gaining among the German people, and Austria made a bold bid for the continued headship in a reconstructed Germany. Francis Joseph invited the princes of all the German states, as well as the ruling burgomasters of the free cities, to a diet of princes (*Fürstentag*), to discuss the question of a new constitution. This assembly sat at Frankfort Aug. 17 to Sept. 1. The king of Prussia declined to attend it. The great majority of princes assented to the project of the emperor of Austria, according to which a directory of five princes (Austria, Prussia, Bavaria, and two others) was to be at the head of the nation, assisted by a federal council and a federal assembly of 300 members, which was to meet every third year.

Although Prussia was to have an equal number of deputies in the federal assembly, the presidency in the directory and federal council was to remain with Austria. The reform association declared for accepting the new constitution as a step in advance; while all the liberal parties of Germany decidedly rejected it. Soon a foreign complication turned the attention of all parties from the conflict of their schemes of reconstruction to a common defence of the German nationality. Frederick VII. of Denmark, in union with the predominant party of the country, had issued in March, 1863, a patent separating the duchy of Holstein from the common Danish monarchy, in order to unite Schleswig (which until then had been united with Holstein under one constitution) with Denmark proper. The federal diet summoned the Danish government to repeal the patent, as it encroached upon the right of Holstein, and thus of Germany, and threatened, in case of refusal, a "federal execution." On Nov. 15 Frederick VII. died, and was succeeded, according to the stipulation of the London conference of 1852, by Christian IX., who on Nov. 18 proclaimed the incorporation of Schleswig with Denmark. But as the federal diet had never recognized the London conference, the people of the duchies, as well as a number of the smaller German states, recognized Prince Frederick of Augustenburg as duke of Schleswig-Holstein. Public opinion throughout Germany strongly sympathized with this view, but Austria and Prussia decided to stand by the stipulations of 1851 and 1852, and insisted on carrying out the federal execution. The federal diet on Dec. 7, by 8 votes against 7, acceded to their demand and intrusted the execution to Hanover and Saxony. The German troops entered Holstein on Dec. 23, and the Danes withdrew without offering resistance. Prussia and Austria on Dec. 28 moved in the federal diet the occupation of Schleswig, in order to enforce the repeal of the law of Nov. 18. The motion was rejected, because the majority believed the question of succession would be prejudged by its adoption. In defiance of this resolution, Austria and Prussia declared that they would now act in the matter, not as members of the confederation, but as great powers of Europe, and at once (February, 1864) marched their troops into Schleswig. On Feb. 5 the Danes evacuated the strong Dannevirke, and withdrew behind the intrenchments of Düppel, which were stormed by the Prussians on April 18. A peace conference of representatives of the great powers, which met in London on April 25, remained without result. The Danes evacuated Jutland and confined themselves to the islands; but when the Prussians on June 29 occupied Alsen, they gave up all further resistance, and in the preliminary peace concluded in July ceded Schleswig, Holstein, and Lauenburg to Austria and Prussia. The cession, which was confirmed in the definitive peace of Vienna,

Oct. 30, was based entirely on the right of conquest, the question of the lawful succession in the duchies and the claims of the federal diet being ignored. When Prussia after the conclusion of peace called upon Hanover and Saxony to withdraw their troops from Holstein, Saxony showed some intention to resist by force. A collision was averted by a resolution of the federal diet, which in accordance with the demand of Austria and Prussia declared the execution to be ended. The disagreement between Austria and Prussia now began to widen. Austria desired to have the administration of the duchies transferred to Prince Frederick of Augustenburg; Bismarck entered into negotiations concerning the annexation of the duchies to Prussia. The federal diet took an unavailing interest in the cause of Prince Frederick, and finally confined itself to a protest against the illegal solution of the Schleswig-Holstein question, while the crown jurists of Prussia undertook to prove that Christian IX. of Denmark was the lawful duke of Schleswig-Holstein, which therefore, in virtue of the peace of Vienna, belonged to Austria and Prussia. A better understanding between Austria and Prussia appeared to be established when the latter power, in April, 1865, concluded a commercial treaty with the Zollverein. On Aug. 14 the Gastein convention gave Austria the exclusive occupation of Holstein, to Prussia that of Schleswig, and annexed Lauenburg to Prussia. The resolution of another general assembly of deputies of all the German states, which was held at Frankfort in October, and which demanded the convocation of the diet of Schleswig-Holstein, was entirely disregarded by the two great powers. Soon a new difficulty sprang up between Austria and Prussia. The permission given by the Austrian governor of Holstein, Gen. von Gablenz, to hold an anti-Prussian meeting at Altona, Jan. 23, 1866, led to a very angry exchange of diplomatic notes. Austria warned the other states against the ambitious schemes of Prussia in a circular note of March 16, and began to arm. As the states of the second rank did not conceal their entire sympathy with Austria, Prussia in April strengthened her position by an alliance with Italy, and also began to arm. At the same time Prussia made a bid for the sympathy of the masses of the people in the smaller states by moving in the federal diet, on April 9, the convocation of a general national assembly, to be elected by direct and universal suffrage. An understanding arrived at between Prussia and Austria to begin the disarmament on April 25 and 26 failed, as Austria refused to withdraw her army from the Italian frontiers. A peace congress, proposed by England, France, and Russia, likewise failed, because Austria demanded the exclusion of all negotiations concerning the extension of the territory of either disjunct. On June 1 Austria transferred the decision of the Schleswig-Holstein question to

the federal diet. This was regarded by Prussia as a termination of the Gastein convention; her troops were at once marched into Holstein and the Austrian governor of Holstein was invited to reënter into the joint occupation of Schleswig. Austria denounced this act as a violation of the federal constitution, and on June 14 the federal diet, by a majority of 11 against 6, adopted the view of Austria and ordered the mobilization of the entire federal army, except the troops of Prussia. The states voting for this resolution were Austria, Bavaria, Saxony, Hanover, Württemberg, Hesse-Cassel, Hesse-Darmstadt, Nassau, and the small states forming the 16th class. The king of Prussia at once declared that the resolution of the federal diet had exceeded its powers and that Prussia regarded the confederation as dissolved. On the following day, the governments of Hanover, Saxony, and Hesse-Cassel were requested by Prussia to take up the vote of the preceding day, to disarm, and to enter into a new confederation with Prussia, which in that case would guarantee their sovereignty; in case of refusal, the opening of hostilities was announced. The three governments on the same day refused this demand, and on June 16 their territory was occupied by Prussian troops. The brilliant campaign of the Prussians against the Austrians, who had been joined by the Saxon troops, in Bohemia and Moravia (June 23 to July 22), and the capture of federal troops in Thuringia and Saxony of the Main (June 27 to the end of August), completed the dissolution of the confederation and secured the reconstruction of many on an entirely new basis. The preliminary peace of Nikolsburg, confirmed by the definitive peace of Aug. 23, excluded Austria from the confederation provided for the establishment of a new federation of the states N. of the Main, the states S. of the Main, Bavaria, Baden, and Hesse-Darmstadt, and the right to establish a South German confederation of Schleswig-Holstein, Hanover, Nassau, and Frankfort were reserved to Prussia. Even before the definitive peace Prussia had concluded offensive and defensive alliances with Saxony (Aug. 13), Baden (Aug. 17), and Württemberg (Aug. 22). On Aug. 24 the members of the old German confederation from Frankfort had removed, and the work of the federal diet was at an end. The North German Confederation (*Norddeutscher Bund*) was established during the period from Dec. 1866 to Jan. 1871. On Dec. 15 an assembly met in Berlin to draft the constitution of the confederation. The constitution was referred to the confederates, which met on Jan. 1871 and on April 16

votes the draft submitted to it. The king of Prussia, as president of the confederation, appointed Bismarck federal chancellor, and on July 1 the constitution went into operation. In February the South German states had held military conferences in Stuttgart to promote a greater conformity of their army organization with that of Prussia. Baden favored the adoption of the entire Prussian system; and when the other three states declined to go so far, though they admitted the desirability of greater uniformity, Baden concluded a special military convention with Prussia. Next to the adoption of the federal constitution, the most important event in the constituent Reichstag was an interpellation of Herr von Bennigsen, one of the leaders of the liberal party, concerning the right of Prussia to garrison the federal fortress of Luxemburg. The grand duchy of Luxemburg, which formed a part of the old German confederation, showed the most decided opposition to entering the new North German, and Prussia had given her consent for the grand duchy to remain outside of the reconstructed Germany. Soon after negotiations had been begun between France and Holland for a sale of the grand duchy to France, Prussia had entered an emphatic protest against this scheme, and on March 30 the king of Holland had officially denied any intention to sell Luxemburg. The full details of these negotiations only became known officially in consequence of the interpellation of Bennigsen, and created an extraordinary excitement throughout Germany. The expression of public opinion against the transfer of Luxemburg to France was no less decided in the south of Germany than in the north. The grand duchy of Hesse concluded in April a military convention with Prussia, in virtue of which its military system was reorganized according to the Prussian, and the Hessian troops were placed under the chief command of the king. Württemberg also introduced several features of the Prussian system. No doubt could be entertained that, in case of war, northern Germany might safely rely on the support of all the South German states. But a conference of the powers which had signed the London treaty of 1839 found a peaceable solution for the Luxemburg question. The grand duchy was declared neutral territory under the guarantee of all the powers represented at the conference; and the federal fortress was to be razed. This peaceable solution was hastened by the declaration of Bismarck that if the result of the conference should not be favorable to the preservation of peace, he would at once mobilize 900,000 men. On May 28 the ministers of the South German states were invited by Prussia to come to Berlin in order to put the Zollverein's treaty on a safe basis. An agreement was arrived at, according to which, for the legislation on affairs of the Zollverein, the South German states would send a specified number of members to the North German fed-

eral council, and order the election of a proportional number of deputies, who in union with the North German Reichstag would constitute the customs parliament. A new attempt of Napoleon to meddle in the progress of German reconstruction by demanding that, in accordance with one article of the treaty of Prague, the people of northern Schleswig be allowed to express by a plébiscite their preference for Denmark or Germany, was sharply repelled by Prussia, Bismarck declaring that Prussia was unwilling to recognize the right of France to watch over the fulfilment of the treaty of Prague. An interview of Napoleon with the emperor of Austria in August was looked upon as a threatening movement against Germany, and not only the North German states, but even the Germans of Austria, strongly expressed themselves against the endeavors of France to interfere in any way in the internal affairs of the German nation. In the grand duchy of Hesse, the second chamber demanded that the entire grand duchy, instead of only the northern portion as hitherto, be admitted into the North German confederation. In Baden both the government and the chambers expressed a wish to enter the confederation. Bismarck issued a circular note on the demonstrations of public opinion, which he declared to be significant proofs that the national feeling of the Germans would never brook a foreign interference in German affairs, and would never allow the development of the affairs of the German nation to be guided by any other considerations than the national interests of Germany. But while South Germany gave no encouragement to the schemes of Napoleon against the progress of German unity, there remained a widespread dissatisfaction with the policy of Prussia, and an unwillingness to tighten the bonds of union. At the election for the first German customs parliament, the South German party, which opposed any advances toward a closer union, elected 50 out of 89 South German deputies. Even in the grand duchy of Baden it met with an unexpected success. When, in reply to the opening speech of the king of Prussia, the national liberal party moved an address which asked for an enlargement of the functions of the customs parliament, and distinctly hinted at the complete union of north and south, the ultra-conservative feudal party of Prussian deputies, the radical party of progress (*Fortschrittspartei*), the Catholic party, and the socialists united with the South German party and caused its rejection by 186 against 150 votes. The conciliatory but firm attitude of the Prussian government prevented the progress of the centrifugal sentiments in South Germany. The governments of Bavaria and Württemberg, although disinclined to make further concessions on the union question, were on the other hand no less unflinching in the observance of the treaties which regulated their relation to northern Germany. Baden,

[illegible]

the imperial government of Germany replied by breaking off all diplomatic intercourse with the papal court. Thus the relation between the Catholic church and the imperial government at the beginning of 1873 was one of open war. This was particularly the case in the kingdom of Prussia, where the relation between church and state was regulated by a number of new laws which all the bishops positively refused to obey. The government then imposed heavy fines upon the bishops, and in many cases withdrew the support which the ministers and institutions of the church had received from the state government. An interesting correspondence on the subject took place between the pope and the emperor. The pope expressed the hope that the cruel laws against the church did not meet the approbation of the emperor, and asked for his personal interference in behalf of the church; to which the emperor replied that in a constitutional state like Prussia every law required the sanction of the sovereign, and that the former peace between the different Christian churches had been wantonly disturbed by the unlawful conduct of the bishops. A germ of new difficulties between the state governments and the Catholic church was the legal position claimed by the Old Catholics, who maintained that the pope and the bishops who adhered to the decree of the Vatican council had abandoned the Catholic church, and that they alone were entitled to be regarded as the true representatives of that Catholic church which in Germany until 1870 was regarded as one of the state churches. Although the state governments, in view of the comparatively small number of the Old Catholics, declined to accept their view of the ecclesiastical situation, they at the same time refused to treat them as seceders from the Catholic church, and took the ground that the movement was an internal affair of that church, with which the state had no right to meddle. In Prussia, the missionary bishop of the Old Catholics was accordingly recognized in October, 1873, as a bishop of the Catholic church, and as such he at once received a salary from the state. The political changes in France greatly encouraged the hopes of the Catholic opposition in Germany, and in several southern districts of Bavaria led to threatening demonstrations against the very existence of the German empire. As a similar effect was produced by the political attitude of the French government in Italy, the visit of the king of Italy to Berlin was enthusiastically hailed by the liberal parties, both in Italy and in Germany, as an indication that the two governments intended to act in full concert against the common enemy. The relations between the governments of the smaller states and the emperor up to the close of 1873 were friendly, and no serious discrepancy of opinions on any important subject was shown in the deliberations of the federal council.—Among the best historical works on Germany are K. A. Menzel's *Ge-*

*schichte der Deutschen* (8 vols., 1815-'22), and *Neuere Geschichte der Deutschen* (12 vols., 1826-'48); Luden's *Geschichte des deutschen Volkes* (to the 13th century, 12 vols., 1829-'39); and Giesebrecht's *Geschichte der deutschen Kaiserzeit* (vols. i.-iii., 3d ed., 1862-'8).

**GERMANY, Language and Literature of.** The formation, the history, and the philological affinities of the German tongue have been treated at length in the article GERMANIC RACES AND LANGUAGES, and we shall therefore restrict our remarks in this article to a brief sketch of the modern High German language as now spoken and written. In this the five vowels, *a*, *e*, *i* (*y*), *o*, and *u*, sound as in Italian, the sound being lengthened by doubling the vowels: *ā* (or *ae*), when long, is like *a* in *mate*, when short almost like *e* in *met*; *ō* (*oe*), long, is like but somewhat duller than the French *eu* in *feu*, when short it resembles the English *u* in *tub*; *ū* (*ue*) is also duller than the French *u* in *sur* and *ture*. *C* before *e* and *i* (*y*), and *z* always, stands for *tz* or *ts*, as in English *pets*; *ck* for *kk*, as in English *peck*, *suck*; *g* is always hard, generally as in *get*, *gice*, but sometimes almost like German *ch*, as in *cwig*, *icig*; *h* before a vowel has the same sound as in our *has*, *hen*; *ch* is harsher than *h*, and like the Greek *χ* or the Spanish *jota*; *j* sounds like *y* in *yes*; *r* is always whirring; *r*, in German words, has the sound of *r*, and in foreign of the English *r*; *w* sounds like English *r*. *S* has a threefold sound: 1, like the Latin *s*, in the combination *st*, at the end of a syllable, as *fist*, *Fürst*, and in forms derived therefrom, *festest*, *Fürsten*, &c., at the end of words, as in *das*, *gutes*, &c., and when double, as in *nass*, *Wasser*, &c.; 2, much like the English *z*, at the beginning of words, before vowels, and between vowels, as in *Sonne*, *dieser*, &c.; 3, like the English *sh* in *shell*, at the beginning of words before some consonants, as *Scandal* (Latin), *spät*, *still*, &c., though in a part of Germany it is pronounced like the English *s* in *sat*. *Sch* is like the English *sh* in *shell*. *Sz* stands for *ss* after long vowels or at the end of words, and is thus written also in derivative forms, as *masz* and *miaz* from *measen*. *Li* is pronounced like the English *ay* (*yes*); *ou* like *ou* in *our*; *ei* (or *ey*) like *i* in *mine*. *Eu* has a very peculiar sound, approaching the English *oi*, and *äu* is somewhat heavier. *E*, the weakest sound, is most frequently employed: 1, for filling up the transition between consonants, thus, *er liebet* for *liebt* (the latter form is now more common); hence it is often elided, as *nah'n* for *nahen*, as in English *poet'r* for *poet'er*, *heut'n* for *heuten*; 2, for lengthening *i* when that letter precedes it, as in *wieder*, again, distinguishing it from *wider*, against, counter; 3, as a mark of the plural, as *Steine*, stones, from *Stein*. *H*, the weakest consonant, is also used for lengthening a preceding vowel, as in *schr*, *wohl*, &c. Besides *e*, three dentals and three liquids serve for all grammatical inflections. They are *d*, *s*, *t*, and *m*, *n*, *r*; *s*, *m*,

and the latter (*Heliand*, first published in Munich, 1830-'40) preserving the ancient alliterations. A translation of the Psalms by Notker, which dates from about the same period, is regarded as one of the best specimens of old High German literature. The *Ludwigslied*, a psalm in honor of the victory of the Frankish king Louis III. over the Normans about 880, which Herder extols as one of the best specimens of early German poetry, was composed in the old High German dialect by a Frankish churchman. The preservation of the song of Hildebrand, which is associated with the legends of Theodoric and Attila, is also due to churchmen, who transmitted it partly in the old High German and partly in the Low German dialect. Several Latin poems were also based upon Hunnish and Burgundian legends, but with these exceptions the priesthood were generally opposed to the national poetry on account of its pagan associations. Many Latin chroniclers and poets flourished in this and the following period; there was also a Latin poetess, Roswitha, or Helena von Rosow, who wrote Latin religious plays. The learning which flourished under the Saxon emperors was superior to that of the times of Charlemagne. The study of mathematics was next in importance to that of theology and Latin. The Greek language, although it was but little cultivated, was not unknown. From the 10th to the 13th century Germany probably possessed a higher mental cultivation than any other country in Europe, but on the whole it was of a Latin and ecclesiastical cast, and the people had no share in it. In the 12th century appeared a hymn in praise of Hanno, archbishop of Cologne, which Herder calls a truly Pindaric song. Among the last poems which appeared in this era from the pen of churchmen were the *Rolandlied* and the *Alexanderlied*.—In the 12th century poetry passed from the monasteries and ecclesiastical schools to the palaces of princes and the castles of nobles. Most of the poets who then came forward were nobles by birth, some of them princes. Heinrich von Veldeke was the first to introduce into his heroic poem *Eneit*, which he is said to have composed after a French version of Virgil, the spirit of devotion to woman, or *Minne* (an old German word for love, whence the name *Minnesänger*). Veldeke is regarded as the originator of the heroic minstrel song, although he is far surpassed in genius, elevation of thought, and depth of feeling by Wolfram von Eschenbach. The other masters of the heroic muse were Gottfried of Strasbourg, Hartmann von der Aue, and Konrad of Würzburg. Their longer heroic poems treat chiefly of the exploits of Charlemagne and of the story of Arthur and the round table. At the same time they composed many songs. Love was their principal theme, but from a sense of delicacy the name of the lady who was the special object of adoration was never mentioned. Respect for womanhood, which was reckoned among the virtues of the ancient

Germans even in the days of the deepest barbarism, contributed to make the German love songs more reverential than those of the French troubadours. A species peculiar to the bards was called the watch song, consisting in a dialogue between a lover and the sentinel who guards his mistress. Walther von der Vogelweide was the most gifted of these lyric poets. Next to him rank Heinrich von Ofterdingen, Reimar der Alte, Heinrich von Morungen, Gottfried von Neifen, and the Austrian bards Nithard and Tanhäuser. Several hundred of these poets were engaged in wandering from palace to palace and from castle to castle. The minstrels constituted what is called the Swabian school of poetry; the songs were mostly in the Swabian dialect. The accession of the Swabian emperors of the house of Hohenstaufen to the throne of Germany was the signal for the rise of the bardic art (1138). Its golden age was shortly before the fall of that dynasty (1254). The crowning event of the minstrel era was the appearance of the lay of the *Nibelungen*. It was followed by the "Book of Heroes" (*Heldenbuch*), consisting of a collection of fragmentary pieces treating of the same legends as the *Nibelungen*, but mixed up with traditions of the crusades.—Didactic poetry began to be cultivated with some success in the 13th century. The dawn of historical works is heralded by several local chronicles; that of writings on natural history in the so-called *Meinauer Naturlehre*; of popular religious literature in the sermons of David of Augsburg and Berthold of Winterthur; and of works on jurisprudence in compilations of Saxon and Swabian laws (*Sachsenspiegel* and *Schwabenspiegel*). Ulrich von Lichtenstein deploras, in 1275, in his famous poem on *Frauendienst* (devotion to woman), the decline of chivalry, but his attempt to revive its spirit was hopeless. Poetry now passed from the abodes of princes and knights to the homes of burghers and the workshops of artisans; and instead of *Minnesänger* we hear of *Meistersänger*, as the plebeian songsters were called. The 13th century, the greater part of which was so rich in poetical productions, was one of the most unfruitful for the cause of learning. Leibnitz says that the 10th century in Germany was a golden age in that respect compared with the 13th.—In the 14th century Germany possessed several mystic theologians, followers of Meister Eckart, the principal of whom was Johann Tauler (1290–1361), whose sermons and writings contributed to pave the way for the reformation. An important event of this century, in its general influence upon the future development of German literature, was the establishment of the university of Prague in 1348, soon followed by universities in almost all parts of Germany. The last echoes of the period of chivalric poetry were two allegorical romances, *Teuerdank* in verse, and *Weiskünig* in prose (first published at the beginning of the 16th century), of which the emperor Maxi-

Toul, Metz, and Verdun had been wrested from the German empire by France. Disgusted with the successes of his adversaries, Charles resigned the crown. He was succeeded by his brother Ferdinand I. (1556-'64). The imperial authority was rapidly sinking to utter insignificance. France in the west and Turkey in the east were hovering on the borders of Germany, ready on every occasion to foster the internal dissensions of the empire and to conquer from it valuable possessions. The feeble Maximilian II. (1564-'76), the visionary Rudolph II. (1576-1612), and his brother Matthias (1612-'19), were unable to arrest the political decay. The thirty years' war (1618-'48), which devastated and impoverished Germany, destroying all industry and commerce, left the imperial authority completely shattered, and Germany cut up into a multitude of petty states, whose rulers were absolute monarchs in fact, if not in name. The persecutions perpetrated by Ferdinand II. (1619-'37) on his Protestant subjects almost equalled those of Philip II. of Spain. The peace of Westphalia (1648), concluded by Ferdinand III. (1637-'57), tore Alsace from the German empire. Under the pedantic and feeble-minded Leopold I. (1658-1705) Germany took part in the coalition against the rising power of France, but, although successful in war, did not obtain any signal advantages by the peace. From that time the title of German emperor appeared only as an empty surname of the rulers of Austria (Joseph I., Charles VI., Francis I., the husband of Maria Theresa, whose enemy, Charles Albert of Bavaria, was also crowned as Charles VII., &c.). In fact, Germany was merely a maze of little despotisms, among which a few larger states were endeavoring to obtain a voice in the councils of Europe. Prussia (a kingdom since 1701), through the genius of Frederick the Great, established a great Protestant power, able to cope with Austria, but at the same time anxious to prevent the reconstruction of a great united empire. Thus the attempts of the emperor Joseph II. (1765-'90, or rather 1780-'90, when he reigned himself) to reestablish the imperial authority in southern Germany were baffled by Prussia. At last the tempest of the French revolution prostrated the tottering fabric of the German empire. Vanquished by the armies of France, the emperor Francis II., son and successor (1792) of Leopold II., ceded by the treaties of Campo Formio (1797) and Lunéville (1801) the country on the left bank of the Rhine. The petty rulers who lost their possessions in this way were indemnified with the territories of ecclesiastical princes. In 1805 several states seceded from the empire and became allies of France; and when at last, in 1806, a number of German states formed the Rhenish confederation under the protectorate of Napoleon, the emperor Francis resigned the German crown, and the empire was formally dissolved. A number of the smaller territories

were annexed to the larger states, and most of the free cities, which while under the nominal authority of the emperors had enjoyed a sort of republican government, lost their independence. The efforts of Prussia to oppose to this confederation a North German league having been frustrated, nearly the whole of Germany, with the exception of Austria and Prussia, was reduced to a state of French vassalage. The minions of the emperor Napoleon ruled the country with an iron rod, and if they removed many of the most glaring remnants of feudal despotism, they introduced in their stead all the abuses of an irresponsible military regime, and carried their extortions to a frightful extent. The sums drawn from Germany by Napoleon under the designation of contributions or subsidies must be counted by hundreds of millions. The independence of the country was reestablished by the coalition of Austria, Russia, Prussia, Sweden, and Great Britain (1813-'15). A reconstruction of the old empire having been rendered impossible by the position which Prussia had assumed, a confederation was formed by all those states which had contrived to maintain their sovereignty during the Napoleonic troubles (June 8, 1815). Their number, which had exceeded 300 at the time of the dissolution of the empire, had then been reduced to less than 40, and a further reduction was made afterward by the extinction of several petty dynasties. The enthusiastic hope of the German people that Germany would once more appear as a powerful united nation was sorely disappointed. The diet, being only a permanent convention of the representatives of princes, all jealous of their individual sovereignty and unwilling to recognize the claims of the nation, became an abject tool of political oppression, and a harmonious coöperation of states existed only in regard to repressive measures against all progressive movements ever the people of a single state sought to obtain free institutions, the diet refused to interfere in favor of absolute power. None of the promises made in the act of confederation in regard to common legislation, a common currency, a common system, &c., were fulfilled. In this respect was due to the selfishness of the states. Thus the Prussian king, who had a large portion of the empire under his dominion, insisted on common laws, and secured great advantages to himself, but he kept alive the longings for a national union. The French revolution found an echo in the hearts of the states, whose rulers were unwilling to written constitutions to limit their arbitrary political life began in the southwestern states, and after the Prussian throne of Frederick William III. (1840), in northern Germany, the people became more and more discontented while in Austria the emperor was suppressed by the

turnich. Immediately on the downfall of the Orleans dynasty in France (Feb. 24, 1848), insurrections broke out in all the German states. The princes, unable to resist these movements, hastened to yield to the popular demands. A national congress of representatives of the people (German parliament) was convoked by a provisional self-constituted assembly (*Vorparlament*), and met at Frankfort, May 18, 1848. It formed a provisional national government, consisting of a vicar of the empire (*Reichsverweser*) and a ministry. Archduke John of Austria was elected vicar, June 29; but in spite of his professions of zeal for national liberty and union, it soon became evident that his principal aim was the frustration of all energetic action on the part of the parliament. Distracted by the troubles in Holstein, which Denmark endeavored to wrest entirely from its connection with the German confederation, the parliament made but slow progress in framing a national constitution. When at last the bill of rights had been agreed upon (December, 1848), the counter-revolution had already been victorious in Austria and Prussia, and it became apparent that these great powers would not submit to a constitution framed by the popular congress. Then a strong party began to advocate the exclusion of Austria from the new empire. This party, whose principal leader was Gagern, prevailed in the parliament, and elected the king of Prussia German emperor (March 28, 1849); but he declined the honor. Despairing of success, a number of members of parliament resigned their position, thus giving a majority to the democratic party, who elected a provisional regency of the empire, consisting of Raveaux, Vogt, Schüler, II. Simon, and Becher. Reduced to less than one third of its original number, the parliament adjourned to Stuttgart, May 30, 1849, and endeavored to raise a popular revolution in favor of the new national constitution. But only the people of Baden, a small part of Würtemberg, and the Palatinate (Bavaria) followed the example of Saxony, which had already risen in revolution. The insurrection at Dresden had been suppressed after a sanguinary battle by Prussian soldiery; and the revolution in Baden, although successful for a few weeks, was likewise crushed in a brief campaign by the Prussian army (June). The rump parliament of Stuttgart had in the mean time been forcibly dissolved by the government of Würtemberg. Having thus got rid of all revolutionary support, the Prussian government attempted to obtain the mastership of Germany on its own account. Austria, almost prostrated at the time by the Hungarian war, would have been able to offer little or no resistance to such a movement if carried on energetically and rapidly; but the Prussian government was no match for the bold and shrewd Prince Schwarzenberg, at that time the soul of the Austrian government. In March, 1850, Prussia assembled at Erfurt a new parliament of representatives of those petty states which were too powerless to resist its demands, and a sort of federal constitution was adopted by it, but never obtained any real existence. To cut short all further attempts of Prussia, Austria convoked the old diet, which had been formally dissolved in 1848. Prussia refusing to recognize the diet, a hostile conflict between Austria and Prussia seemed almost inevitable. The armies of both were marching to Hesse-Cassel, and a skirmish of the outposts had taken place near Bronzell (Nov. 8, 1850), when suddenly the Prussian government lost courage and submitted to all the demands of Austria. The first fruits of the restoration of the diet were the intervention in Schleswig-Holstein in favor of Denmark, the abolition of the national bill of rights and of free constitutions in several of the smaller states, and the sale by auction of the national navy which had been created by voluntary contributions of the people during the revolution. While in these questions the influence of Austria prevailed, Prussia balanced its loss of political power by the enlargement of its commercial influence. Hanover became a member of the Zollverein (September, 1851), and was soon followed by Oldenburg and Schaumburg-Lippe. The efforts of Austria to enter the Zollverein, in order to destroy the Prussian influence even there, were successfully resisted by Prussia, but a postal and telegraph union of all German states was accomplished. During the eastern war (1853-'6) the German confederation followed a vacillating policy, swaying to and fro between Austria and Prussia. In April, 1854, those two powers concluded a treaty of alliance, guaranteeing to each other their respective possessions against all enemies whatever. The diet joined in this treaty July 24, and in December added another clause, promising the assistance of all Germany to Austria if its army of occupation in the Danubian principalities should be attacked. Preparation for war was resolved upon by the diet, Feb. 8, 1855. After that the position of Prussia toward Austria became more reserved, and Austria, despairing of active assistance on the part of the confederation, was compelled to relinquish its intention to take part in the war against Russia. In November, 1856, the diet adopted a resolution promising to assist Prussia in its attempts to reconquer Neufchâtel, but the proffered assistance was not required. In 1857 the interference of the diet was requested against the attempts of Denmark to merge the duchies of Holstein and Lauenburg completely in the Danish kingdom. After long hesitation and delay a resolution was adopted in 1858, by which the Danish government was compelled to submit its project of a new political organization to the legislative assemblies of the duchies. When, in the beginning of 1859, difficulties arose between France and Austria on account of the state of Italy, a violent anti-Napoleonic feeling

manifested itself in Germany. The Prussian government, though willing to defend Austria's German provinces, and even the Lombardo-Venetian kingdom, under certain restrictions, would not stir unless it should obtain the military leadership of all Germany, irrespective of all limitations contained in the act of confederation. After long and angry discussions the leadership was conceded to Prussia by the smaller states. A circular despatch of the Russian government, covertly threatening Germany if it should interfere in the Italian war, had no effect but the assumption by Prussia of a more defiant attitude toward France, and the issue of an order by the prince regent to mobilize two thirds of the Prussian army (June, 1859). A few days later, the Prussian delegate in the diet moved that two federal army corps under the command of Bavaria be stationed on the upper Rhine, and one Prussian corps on the Main, and that the 9th and 10th federal army corps be united with the Prussian army. This motion was followed by another, to the effect that the diet should appoint a commander-in-chief of the non-Prussian and non-Austrian army corps. Thus the German confederation appeared to be on the very point of waging war against France, under Prussian leadership, when all at once Austria, unwilling to sacrifice its preponderating influence in Germany to the doubtful project of preserving its Italian provinces, introduced in the diet a resolution to mobilize the whole federal army, and to appoint the Prussian prince regent commander-in-chief, subject to the control of the diet, or rather of Austria, the latter being always certain of a majority in the diet. This movement at once neutralized all advantages Prussia had obtained. And when the preliminaries of peace were agreed upon by the emperors of France and Austria at Villafranca, July 11, the dissension and jealousy between Austria and Prussia, those great impediments to German unity, were more apparent than ever before. A passage in the Austrian emperor's proclamation of peace, in which he asserted that his natural allies had forsaken him, and that the neutral powers would have imposed upon him less favorable terms of peace than were offered by his adversary, gave rise to an acrimonious correspondence between the Austrian and Prussian governments. The latter succeeded in proving that the assertion of the emperor had no foundation in fact, and that he had been purposely misled by false representations of the French ruler at the interview of Villafranca. This singular discovery did not render the feeling of Austria any more friendly toward Prussia. A paper war was carried on by the presses of southern and northern Germany, and while the governments of those petty states who had been the most forward in their hostile demonstrations against France were eagerly courting the favor of Napoleon III., the most sinister threats against Prussia came from Vienna, Munich, and

Carlsruhe. The opinion became prevalent: that Austria having been humbled by France, if a war for the conquest of the left bank of the Rhine should be waged by France against Prussia, the latter would not obtain any assistance either from Austria or the smaller German states. The hostility of the two great sections of Germany manifested itself in sanguinary riots in the mixed Prussian and Austrian garrison of the federal capital (Aug. 6-8). Feeble movements were initiated by the liberal party to arrest the progress of disunion, and to prompt the Prussian government to take the lead in reforming the federal constitution. But Prussia, disheartened and unwilling openly to oppose the influence of Austria, declined the destiny which the liberal party pressed upon it, and would promise nothing more than the promotion of liberal institutions by the power of its example. Austria, on the other hand, made some show of concessions to the popular wishes, in order to divide the current of the sympathies of the popular party in Germany. A committee was appointed by the emperor (August) to draw up a constitution on the basis of provincial representation for the Austrian empire. At the same time a movement was initiated in Bavaria, the object of which was the creation of a second federation of the central German states, a third great power within Germany. This idea had been promoted by Bavaria in 1848, and then led to confusion and disunion. Withstanding the discouraging conduct of the Prussian government, the liberal party in many on Sept. 16 established a new assembly, the *Nationalverein*, to promote in all the particular details the interests of the confederation (*Staatsreform*), a compact federal state with a strong centralization (*Bundesstaat*), under the leadership of Prussia. Prussia in no way expressed its opposition to this project, but it soon took up the opposition in the federal diet the previous year, and its allies. It moved on the 10th of October the federal constitution of Hesse-Cassel, which in 1852 had been abolished, to be restored. Hesse-Cassel fully approved the project, but in the federal diet the project led to its rejection. In May, 1860, the king of Prussia for a reform of the constitution of the German confederation was wise rejected. The attitude of Austria toward the central and national principles, which was what mitigated by the fundamental law in Austria, which appeared as a constitutional principle. Prussia greatly offended the conservative principles proclaimed by William I., who on Jan. 2, 1861, his brother Frederick V, the Saxon minister V, ardent champions of

presented to Prussia a new project of the federal constitution, according to which a representation of the German nation at the federal diet was to be created by the establishment of an assembly of delegates chosen by the diets of the several states. Austria declared its readiness to accept this project, which gave to Austria and Prussia an equal number of delegates, if she should be allowed to enter the confederation with her entire territory. Prussia in a note of Dec. 20 declared it to be impracticable, and instead advocated the establishment of a federal state, on the plan which had been tried ten years before. This idea was promptly rejected by all the middle states in February, 1862, on the ground that it would involve the loss of their sovereignty. In August they united with Austria in submitting another plan of reform, according to which an assembly of delegates of the several German diets was to be convoked at Frankfort for the special purpose of deliberating on some reforms in the civil and commercial legislation of the German states. An assembly of liberal German deputies, held in September at Weimar, declared against this plan as wholly unsatisfactory, while on the other hand it was approved by the new national reform association (*Reformverein*), which in October was organized at Frankfort as the organ of those who unconditionally opposed the exclusion of Austria from Germany and the establishment of a Prussian leadership. In the federal diet, in January, 1863, it was defeated by a small majority. In the mean while the incessant conflicts between the Prussian liberals and their ultra-reactionary government had led, in September, to the entrance into the ministry of Otto von Bismarck, who soon after became its president and minister of foreign affairs. The uncompromising firmness with which he opposed the views of the Prussian diet on a reduction of the military budget filled even the Prussian friends of national unity with despair. Little was known of the ultimate plans of Bismarck with regard to German unity; but it was apparent that Prussia desired to be emancipated from the federal diet, and that her plans would henceforth be pushed with greater energy than at any previous time. The union movement was steadily gaining among the German people, and Austria made a bold bid for the continued headship in a reconstructed Germany. Francis Joseph invited the princes of all the German states, as well as the ruling burgomasters of the free cities, to a diet of princes (*Fürstentag*), to discuss the question of a new constitution. This assembly sat at Frankfort Aug. 17 to Sept. 1. The king of Prussia declined to attend it. The great majority of princes assented to the project of the emperor of Austria, according to which a directory of five princes (Austria, Prussia, Bavaria, and two others) was to be at the head of the nation, assisted by a federal council and a federal assembly of 300 members, which was to meet every third year.

Although Prussia was to have an equal number of deputies in the federal assembly, the presidency in the directory and federal council was to remain with Austria. The reform association declared for accepting the new constitution as a step in advance; while all the liberal parties of Germany decidedly rejected it. Soon a foreign complication turned the attention of all parties from the conflict of their schemes of reconstruction to a common defence of the German nationality. Frederick VII. of Denmark, in union with the predominant party of the country, had issued in March, 1863, a patent separating the duchy of Holstein from the common Danish monarchy, in order to unite Schleswig (which until then had been united with Holstein under one constitution) with Denmark proper. The federal diet summoned the Danish government to repeal the patent, as it encroached upon the right of Holstein, and thus of Germany, and threatened, in case of refusal, a "federal execution." On Nov. 15 Frederick VII. died, and was succeeded, according to the stipulation of the London conference of 1852, by Christian IX., who on Nov. 18 proclaimed the incorporation of Schleswig with Denmark. But as the federal diet had never recognized the London conference, the people of the duchies, as well as a number of the smaller German states, recognized Prince Frederick of Augustenburg as duke of Schleswig-Holstein. Public opinion throughout Germany strongly sympathized with this view, but Austria and Prussia decided to stand by the stipulations of 1851 and 1852, and insisted on carrying out the federal execution. The federal diet on Dec. 7, by 8 votes against 7, acceded to their demand and intrusted the execution to Hanover and Saxony. The German troops entered Holstein on Dec. 23, and the Danes withdrew without offering resistance. Prussia and Austria on Dec. 28 moved in the federal diet the occupation of Schleswig, in order to enforce the repeal of the law of Nov. 18. The motion was rejected, because the majority believed the question of succession would be prejudged by its adoption. In defiance of this resolution, Austria and Prussia declared that they would now act in the matter, not as members of the confederation, but as great powers of Europe, and at once (February, 1864) marched their troops into Schleswig. On Feb. 5 the Danes evacuated the strong Dannevirke, and withdrew behind the intrenchments of Düppel, which were stormed by the Prussians on April 18. A peace conference of representatives of the great powers, which met in London on April 25, remained without result. The Danes evacuated Jutland and confined themselves to the islands; but when the Prussians on June 29 occupied Alsen, they gave up all further resistance, and in the preliminary peace concluded in July ceded Schleswig, Holstein, and Lauenburg to Austria and Prussia. The cession, which was confirmed in the definitive peace of Vienna,

Oct. 30, was based entirely on the right of conquest, the question of the lawful succession in the duchies and the claims of the federal diet being ignored. When Prussia after the conclusion of peace called upon Hanover and Saxony to withdraw their troops from Holstein, Saxony showed some intention to resist by force. A collision was averted by a resolution of the federal diet, which in accordance with the demand of Austria and Prussia declared the execution to be ended. The disagreement between Austria and Prussia now began to widen. Austria desired to have the administration of the duchies transferred to Prince Frederick of Augustenburg; Bismarck entered into negotiations concerning the annexation of the duchies to Prussia. The federal diet took an unavailing interest in the cause of Prince Frederick, and finally confined itself to a protest against the illegal solution of the Schleswig-Holstein question, while the crown jurists of Prussia undertook to prove that Christian IX. of Denmark was the lawful duke of Schleswig-Holstein, which therefore, in virtue of the peace of Vienna, belonged to Austria and Prussia. A better understanding between Austria and Prussia appeared to be established when the latter power, in April, 1865, concluded a commercial treaty with the Zollverein. On Aug. 14 the Gastein convention gave Austria the exclusive occupation of Holstein, to Prussia that of Schleswig, and annexed Lauenburg to Prussia. The resolution of another general assembly of deputies of all the German states, which was held at Frankfort in October, and which demanded the convocation of the diet of Schleswig-Holstein, was entirely disregarded by the two great powers. Soon a new difficulty sprang up between Austria and Prussia. The permission given by the Austrian governor of Holstein, Gen. von Gablenz, to hold an anti-Prussian meeting at Altona, Jan. 23, 1866, led to a very angry exchange of diplomatic notes. Austria warned the other states against the ambitious schemes of Prussia in a circular note of March 16, and began to arm. As the states of the second rank did not conceal their entire sympathy with Austria, Prussia in April strengthened her position by an alliance with Italy, and also began to arm. At the same time Prussia made a bid for the sympathy of the masses of the people in the smaller states by moving in the federal diet, on April 9, the convocation of a general national assembly, to be elected by direct and universal suffrage. An understanding arrived at between Prussia and Austria to begin the disarmament on April 25 and 26 failed, as Austria refused to withdraw her army from the Italian frontiers. A peace congress, proposed by England, France, and Russia, likewise failed, because Austria demanded the exclusion of all negotiations concerning the extension of the territory of either dissonant. On June 1 Austria transferred the decision of the Schleswig-Holstein question to

the federal diet. This was regarded by Prussia as a termination of the Gastein convention; her troops were at once marched into Holstein, and the Austrian governor of Holstein was invited to reënter into the joint occupation of Schleswig. Austria denounced this act as a violation of the federal constitution, and on June 14 the federal diet, by a majority of 9 against 6, adopted the view of Austria and ordered the mobilization of the entire federal army, except the troops of Prussia. The states voting for this resolution were Austria, Bavaria, Saxony, Hanover, Würtemberg, Hesse-Cassel, Hesse-Darmstadt, Nassau, and the small states forming the 16th class. The representative of Prussia at once declared that the majority of the federal diet had exceeded its authority, and that Prussia regarded the confederation as dissolved. On the following day, the governments of Hanover, Saxony, and Hesse-Cassel were requested by Prussia to take back their vote of the preceding day, to disarm, and to enter into a new confederation with Prussia, which in that case would guarantee their sovereignty; in case of refusal, the immediate opening of hostilities was announced. The three governments on the same day refused this demand, and on June 16 their territory was occupied by Prussian troops. The brilliant campaign of the Prussians (see PRUSSIA) against the Austrians, who had been joined by the Saxon troops, in Bohemia and Moravia (June 23 to July 22), and against the other federal troops in Thuringia and in the region of the Main (June 27 to the beginning of August), completed the dissolution of the confederation and secured the reconstruction of Germany on an entirely new basis. The preliminary peace of Nikolsburg, July 26, which was confirmed by the definitive peace of Prague, Aug. 23, excluded Austria from Germany, and provided for the establishment of a new confederation of the states N. of the Main. The states S. of the Main, Bavaria, Baden, and Hesse-Cassel, were invited to establish a Southern German Confederation with Schleswig-Holstein. Hanover, Nassau, and Frankfort were incorporated into Prussia. Even before the conclusion of the definitive peace Prussia had secured offensive and defensive alliances with Saxony, Würtemberg (Aug. 18), Baden (Aug. 17), and Hesse-Darmstadt (Aug. 22). On Aug. 24 the last representatives of the old German confederation from Frankfort had removed to Berlin, and declared the work of the federal diet at an end. The North German Confederation (*Norddeutscher Bund*) was established by treaties between Prussia and the other states during the period from Aug. 1 to Dec. 15. On Dec. 15 an assembly of plenipotentiaries met in Berlin to draft the constitution of the confederation, which was referred to the constituent North German Diet, which met in Berlin on Jan. 18, 1867, and on April 16 adopted by

votes the draft submitted to it. The king of Prussia, as president of the confederation, appointed Bismarck federal chancellor, and on July 1 the constitution went into operation. In February the South German states had held military conferences in Stuttgart to promote a greater conformity of their army organization with that of Prussia. Baden favored the adoption of the entire Prussian system; and when the other three states declined to go so far, though they admitted the desirability of greater uniformity, Baden concluded a special military convention with Prussia. Next to the adoption of the federal constitution, the most important event in the constituent Reichstag was an interpellation of Herr von Bennigsen, one of the leaders of the liberal party, concerning the right of Prussia to garrison the federal fortress of Luxemburg. The grand duchy of Luxemburg, which formed a part of the old German confederation, showed the most decided opposition to entering the new North German, and Prussia had given her consent for the grand duchy to remain outside of the reconstructed Germany. Soon after negotiations had been begun between France and Holland for a sale of the grand duchy to France, Prussia had entered an emphatic protest against this scheme, and on March 30 the king of Holland had officially denied any intention to sell Luxemburg. The full details of these negotiations only became known officially in consequence of the interpellation of Bennigsen, and created an extraordinary excitement throughout Germany. The expression of public opinion against the transfer of Luxemburg to France was no less decided in the south of Germany than in the north. The grand duchy of Hesse concluded in April a military convention with Prussia, in virtue of which its military system was reorganized according to the Prussian, and the Hessian troops were placed under the chief command of the king. Württemberg also introduced several features of the Prussian system. No doubt could be entertained that, in case of war, northern Germany might safely rely on the support of all the South German states. But a conference of the powers which had signed the London treaty of 1839 found a peaceable solution for the Luxemburg question. The grand duchy was declared neutral territory under the guarantee of all the powers represented at the conference; and the federal fortress was to be razed. This peaceable solution was hastened by the declaration of Bismarck that if the result of the conference should not be favorable to the preservation of peace, he would at once mobilize 900,000 men. On May 28 the ministers of the South German states were invited by Prussia to come to Berlin in order to put the Zollverein's treaty on a safe basis. An agreement was arrived at, according to which, for the legislation on affairs of the Zollverein, the South German states would send a specified number of members to the North German fed-

eral council, and order the election of a proportional number of deputies, who in union with the North German Reichstag would constitute the customs parliament. A new attempt of Napoleon to meddle in the progress of German reconstruction by demanding that, in accordance with one article of the treaty of Prague, the people of northern Schleswig be allowed to express by a plébiscite their preference for Denmark or Germany, was sharply repelled by Prussia, Bismarck declaring that Prussia was unwilling to recognize the right of France to watch over the fulfilment of the treaty of Prague. An interview of Napoleon with the emperor of Austria in August was looked upon as a threatening movement against Germany, and not only the North German states, but even the Germans of Austria, strongly expressed themselves against the endeavors of France to interfere in any way in the internal affairs of the German nation. In the grand duchy of Hesse, the second chamber demanded that the entire grand duchy, instead of only the northern portion as hitherto, be admitted into the North German confederation. In Baden both the government and the chambers expressed a wish to enter the confederation. Bismarck issued a circular note on the demonstrations of public opinion, which he declared to be significant proofs that the national feeling of the Germans would never brook a foreign interference in German affairs, and would never allow the development of the affairs of the German nation to be guided by any other considerations than the national interests of Germany. But while South Germany gave no encouragement to the schemes of Napoleon against the progress of German unity, there remained a widespread dissatisfaction with the policy of Prussia, and an unwillingness to tighten the bonds of union. At the election for the first German customs parliament, the South German party, which opposed any advances toward a closer union, elected 50 out of 89 South German deputies. Even in the grand duchy of Baden it met with an unexpected success. When, in reply to the opening speech of the king of Prussia, the national liberal party moved an address which asked for an enlargement of the functions of the customs parliament, and distinctly hinted at the complete union of north and south, the ultra-conservative feudal party of Prussian deputies, the radical party of progress (*Fortschrittspartei*), the Catholic party, and the socialists united with the South German party and caused its rejection by 186 against 150 votes. The conciliatory but firm attitude of the Prussian government prevented the progress of the centrifugal sentiments in South Germany. The governments of Bavaria and Württemberg, although disinclined to make further concessions on the union question, were on the other hand no less unflinching in the observance of the treaties which regulated their relation to northern Germany. Baden,

on May 25, 1869, concluded a new military convention with Prussia, which established an entire uniformity between the armies of Baden and Prussia. The North German Reichstag expressed a decided opinion in favor of restricting the right of particular states and enlarging the functions of the central authorities. The first six months of the year 1870 were unusually quiet, and it was the common opinion that great changes in the relation of the four South German states to the North German confederation were not likely to be made for a long time to come, when suddenly the action of France precipitated the final solution of the German question. The Spanish crown having been offered to Prince Leopold of Hohenzollern, and rejected, the emperor Napoleon demanded the guarantee of Prussia against its acceptance at any time thereafter by any prince of its house. This being scornfully refused, war was at once declared by France (July 19, 1870), and, after a brilliant series of victories for the Germans and almost uninterrupted defeats for the French, was in effect concluded by the preliminary peace of Versailles, Feb. 26, 1871. (See FRANCE.) In this war all the states both of North and South Germany, except Austria, participated; and in view of the common danger through which all had passed, and the common victory which all had won, the governments and the people of South Germany now waived any further opposition to a consolidation of all the German states under the leadership of Prussia. On Nov. 15, 1870, a treaty was concluded between the North German confederation, Baden, and Hesse concerning the establishment of the German confederation (*Deutscher Bund*); on Nov. 23 the entrance of Bavaria into the confederation was regulated by treaty; on Nov. 25, that of Württemberg. Bavaria asked and received important concessions, which to many unionists appeared to be going too far in favor of particularism; but the treaty was unanimously ratified by the federal council of the North German confederation, and by the Reichstag by 195 against 32 votes. On Dec. 3 the king of Bavaria invited the king of Prussia to restore the dignity of German emperor; most of the other governments gave their assent to the proposition before Dec. 8. In the name of the federal council the federal chancellor on Dec. 9 moved in the Reichstag, and the motion was adopted on the following day, that the German confederation assume the name German empire, and the king of Prussia, as president of the confederation, the title emperor of Germany. On Jan. 18, 1871, the restoration of the imperial dignity was solemnly proclaimed by the king of Prussia at Versailles; on March 21 the first German Reichstag assembled at Berlin, and was opened by the emperor in person. On April 14 this Reichstag ratified the constitution of the German empire, with but three dissenting votes; and on May 4 the constitution went into

operation. By the peace of Versailles Germany recovered the province of Alsace and the German-speaking district of Lorraine. The definitive peace was concluded at Frankfurt on May 10, and on June 9 the new *Reichsland* of Alsace-Lorraine was proclaimed as incorporated with Germany. The majority of the Reichstag, in full harmony with the imperial government and the majority of the federal council, was intent upon consolidating the new empire by centralizing the functions of the central authorities. As two German states, the grand duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz, were still without a constitutional government, the Reichstag on Nov. 8 adopted a resolution of the deputy Büsing that a German state must in future have a constitutional form of government. On Nov. 10 a motion of Lasker; it was resolved to extend the whole of the civil law within the empire to the imperial legislation. Of the political parties which opposed the advancing consolidation of the empire, by far the most powerful was the Catholic, or the centre, as it was called from the central seats which its representatives occupied in the Reichstag. On the opening of the first session of the Reichstag in March, 1871, they moved an amendment to the address by which the Reichstag replied to the speech from the throne for the protection of the temporal power of the pope. On this question the other parties united against them almost unanimously. The address moved by the majority of the Reichstag was adopted by 243 votes, the minority consisting of the Catholics and a few socialists. The conflict between them and the imperial government became more intense in 1872. One of the principal speeches which the pope had made in 1871 was regarded by the majority of the Reichstag as a direct wish for the overthrow of the empire, and intensified the sore which had been produced by the pope's refusal to recognize the cardinal prince Hohenlohe, whom the German government wished to appoint as ambassador at the papal court. As a result of this opinion that the religious excitement in the Catholic districts of Germany was largely due to the influence of the pope, the Reichstag and federal council adopted a law which provided for the suppression of all the houses of the Jesuits and other religious orders. This law, which took effect in the year 1872, was gradually modified to define which other religious orders were proscribed within its terms; but the Lazarists, ladies of the Sacred Heart, and others shared at once the same fate. The bishops of Germany met in a general conference at Bonn, and bitterly complained of the law, and the pope, in an allocution, expressed terms still more severe in regard to the attitude of the anti-Catholicism.

the imperial government of Germany replied by breaking off all diplomatic intercourse with the papal court. Thus the relation between the Catholic church and the imperial government at the beginning of 1873 was one of open war. This was particularly the case in the kingdom of Prussia, where the relation between church and state was regulated by a number of new laws which all the bishops positively refused to obey. The government then imposed heavy fines upon the bishops, and in many cases withdrew the support which the ministers and institutions of the church had received from the state government. An interesting correspondence on the subject took place between the pope and the emperor. The pope expressed the hope that the cruel laws against the church did not meet the approbation of the emperor, and asked for his personal interference in behalf of the church; to which the emperor replied that in a constitutional state like Prussia every law required the sanction of the sovereign, and that the former peace between the different Christian churches had been wantonly disturbed by the unlawful conduct of the bishops. A germ of new difficulties between the state governments and the Catholic church was the legal position claimed by the Old Catholics, who maintained that the pope and the bishops who adhered to the decree of the Vatican council had abandoned the Catholic church, and that they alone were entitled to be regarded as the true representatives of that Catholic church which in Germany until 1870 was regarded as one of the state churches. Although the state governments, in view of the comparatively small number of the Old Catholics, declined to accept their view of the ecclesiastical situation, they at the same time refused to treat them as seceders from the Catholic church, and took the ground that the movement was an internal affair of that church, with which the state had no right to meddle. In Prussia, the missionary bishop of the Old Catholics was accordingly recognized in October, 1873, as a bishop of the Catholic church, and as such he at once received a salary from the state. The political changes in France greatly encouraged the hopes of the Catholic opposition in Germany, and in several southern districts of Bavaria led to threatening demonstrations against the very existence of the German empire. As a similar effect was produced by the political attitude of the French government in Italy, the visit of the king of Italy to Berlin was enthusiastically hailed by the liberal parties, both in Italy and in Germany, as an indication that the two governments intended to act in full concert against the common enemy. The relations between the governments of the smaller states and the emperor up to the close of 1873 were friendly, and no serious discrepancy of opinions on any important subject was shown in the deliberations of the federal council.—Among the best historical works on Germany are K. A. Menzel's *Ge-*

*schichte der Deutschen* (8 vols., 1815-'22), and *Neuere Geschichte der Deutschen* (12 vols., 1826-'48); Luden's *Geschichte des deutschen Volkes* (to the 18th century, 12 vols., 1829-'39); and Giesebrecht's *Geschichte der deutschen Kaiserzeit* (vols. i.-iii., 3d ed., 1862-'8).

**GERMANY, Language and Literature of.** The formation, the history, and the philological affinities of the German tongue have been treated at length in the article GERMANIC RACES AND LANGUAGES, and we shall therefore restrict our remarks in this article to a brief sketch of the modern High German language as now spoken and written. In this the five vowels, *a*, *e*, *i* (*y*), *o*, and *u*, sound as in Italian, the sound being lengthened by doubling the vowels: *ä* (or *ae*), when long, is like *a* in *mate*, when short almost like *e* in *met*; *ö* (*oe*), long, is like but somewhat duller than the French *eu* in *feu*, when short it resembles the English *u* in *tub*; *ü* (*ue*) is also duller than the French *u* in *sur* and *ture*. *C* before *e* and *i* (*y*), and *s* always, stands for *ts* or *te*, as in English *pets*; *ck* for *kk*, as in English *peck*, *suck*; *g* is always hard, generally as in *get*, *give*, but sometimes almost like German *ch*, as in *ewig*, *weg*; *h* before a vowel has the same sound as in our *has*, *hen*; *ch* is harsher than *h*, and like the Greek *χ* or the Spanish *jota*; *j* sounds like *y* in *yes*; *r* is always whirring; *v*, in German words, has the sound of *f*, and in foreign of the English *v*; *w* sounds like English *r*. *S* has a threefold sound: 1, like the Latin *s*, in the combination *st*, at the end of a syllable, as *fest*, *Fürst*, and in forms derived therefrom, *festest*, *Fürsten*, &c., at the end of words, as in *das*, *gutes*, &c., and when double, as in *nass*, *Wasser*, &c.; 2, much like the English *s*, at the beginning of words, before vowels, and between vowels, as in *Sonne*, *dieser*, &c.; 3, like the English *sh* in *shell*, at the beginning of words before some consonants, as *Scandal* (Latin), *spät*, *still*, &c., though in a part of Germany it is pronounced like the English *s* in *sea*. *Sch* is like the English *sh* in *shell*. *ss* stands for *ss* after long vowels or at the end of words, and is thus written also in derivative forms, as *mass* and *miss* from *meissen*. *ai* is pronounced like the English *ay* (*yes*); *au* like *ou* in *our*; *ei* (or *ey*) like *i* in *mine*. *Eu* has a very peculiar sound, approaching the English *oi*, and *äu* is somewhat heavier. *E*, the weakest sound, is most frequently employed: 1, for filling up the transition between consonants, thus, *er liebet* for *liebt* (the latter form is now more common); hence it is often elided, as *nah'n* for *nahen*, as in English *pow'r* for *power*, *hear'n* for *heaven*; 2, for lengthening; when that letter precedes it, as in *wieder*, again, distinguishing it from *wider*, against, counter; 3, as a mark of the plural, as *Steine*, stones, from *Stein*. *H*, the weakest consonant, is also used for lengthening a preceding vowel, as in *sehr*, *wohl*, &c. Besides *a*, three dentals and three liquids serve for all grammatical inflections. They are *d*, *s*, *t*, and *m*, *n*, *r*; *a*, *m*,

and the latter (*Heliand*, first published in Munich, 1830-'40) preserving the ancient alliterations. A translation of the Psalms by Notker, which dates from about the same period, is regarded as one of the best specimens of old High German literature. The *Ludwigslied*, a pæan in honor of the victory of the Frankish king Louis III. over the Normans about 880, which Herder extols as one of the best specimens of early German poetry, was composed in the old High German dialect by a Frankish churchman. The preservation of the song of Hildebrand, which is associated with the legends of Theodoric and Attila, is also due to churchmen, who transmitted it partly in the old High German and partly in the Low German dialect. Several Latin poems were also based upon Hunnish and Burgundian legends, but with these exceptions the priesthood were generally opposed to the national poetry on account of its pagan associations. Many Latin chroniclers and poets flourished in this and the following period; there was also a Latin poetess, Roswitha, or Helena von Rossow, who wrote Latin religious plays. The learning which flourished under the Saxon emperors was superior to that of the times of Charlemagne. The study of mathematics was next in importance to that of theology and Latin. The Greek language, although it was but little cultivated, was not unknown. From the 10th to the 13th century Germany probably possessed a higher mental cultivation than any other country in Europe, but on the whole it was of a Latin and ecclesiastical cast, and the people had no share in it. In the 12th century appeared a hymn in praise of Hanno, archbishop of Cologne, which Herder calls a truly Pindaric song. Among the last poems which appeared in this era from the pen of churchmen were the *Rolandlied* and the *Alexanderlied*.—In the 12th century poetry passed from the monasteries and ecclesiastical schools to the palaces of princes and the castles of nobles. Most of the poets who then came forward were nobles by birth, some of them princes. Heinrich von Veldeke was the first to introduce into his heroic poem *Encit*, which he is said to have composed after a French version of Virgil, the spirit of devotion to woman, or *Minne* (an old German word for love, whence the name *Minnesänger*). Veldeke is regarded as the originator of the heroic minstrel song, although he is far surpassed in genius, elevation of thought, and depth of feeling by Wolfram von Eschenbach. The other masters of the heroic muse were Gottfried of Strasbourg, Hartmann von der Aue, and Konrad of Würzburg. Their longer heroic poems treat chiefly of the exploits of Charlemagne and of the story of Arthur and the round table. At the same time they composed many songs. Love was their principal theme, but from a sense of delicacy the name of the lady who was the special object of adoration was never mentioned. Respect for womanhood, which was reckoned among the virtues of the ancient

Germans even in the days of the deepest barbarism, contributed to make the German love songs more reverential than those of the French troubadours. A species peculiar to the bards was called the watch song, consisting in a dialogue between a lover and the sentinel who guards his mistress. Walther von der Vogelweide was the most gifted of these lyric poets. Next to him rank Heinrich von Ofterdingen, Reimar der Alte, Heinrich von Morungen, Gottfried von Neifen, and the Austrian bards Nithard and Tanhäuser. Several hundred of these poets were engaged in wandering from palace to palace and from castle to castle. The minstrels constituted what is called the Swabian school of poetry; the songs were mostly in the Swabian dialect. The accession of the Swabian emperors of the house of Hohenstaufen to the throne of Germany was the signal for the rise of the bardic art (1138). Its golden age was shortly before the fall of that dynasty (1254). The crowning event of the minstrel era was the appearance of the lay of the *Nibelungen*. It was followed by the "Book of Heroes" (*Heldenbuch*), consisting of a collection of fragmentary pieces treating of the same legends as the *Nibelungen*, but mixed up with traditions of the crusades.—Didactic poetry began to be cultivated with some success in the 13th century. The dawn of historical works is heralded by several local chronicles; that of writings on natural history in the so-called *Meinauer Naturlehre*; of popular religious literature in the sermons of David of Augsburg and Berthold of Winterthur; and of works on jurisprudence in compilations of Saxon and Swabian laws (*Sachsenspiegel* and *Schwabenspiegel*). Ulrich von Lichtenstein deploras, in 1275, in his famous poem on *Frauentrost* (devotion to woman), the decline of chivalry, but his attempt to revive its spirit was hopeless. Poetry now passed from the abodes of princes and knights to the homes of burghers and the workshops of artisans; and instead of *Minnesänger* we hear of *Meistersänger*, as the plebeian songsters were called. The 13th century, the greater part of which was so rich in poetical productions, was one of the most unfruitful for the cause of learning. Leibnitz says that the 10th century in Germany was a golden age in that respect compared with the 13th.—In the 14th century Germany possessed several mystic theologians, followers of Meister Eckart, the principal of whom was Johann Tauler (1290–1361), whose sermons and writings contributed to pave the way for the reformation. An important event of this century, in its general influence upon the future development of German literature, was the establishment of the university of Prague in 1348, soon followed by universities in almost all parts of Germany. The last echoes of the period of chivalric poetry were two allegorical romances, *Truendank* in verse, and *Weiskünig* in prose (first published at the beginning of the 16th century), of which the emperor Maxi-

milian is the hero and probably the author, although Melchior Pfinsing is said to have composed the former romance at the emperor's request. The only good poetry of the 14th and 15th centuries was the spirited songs of Halbsuter and Veit Weber, celebrating the victories of Switzerland over Austria and Burgundy.—The progress of classical culture was stimulated at the opening of the 15th century by the establishment of learned societies and schools in different parts of Germany and the Low Countries. Hegius, Langius, Dringeburg, Reuchlin, Agricola, and other eminent men were among the scholars. Purbach was the first restorer of mathematical science, and his pupil Regiomontanus (Johann Müller) was the greatest mathematician of the 15th century; while Gutenberg was one of its heroes. His invention of the art of printing produced a steadily increasing literary activity, and the books printed in Germany between 1470 and 1500 amounted to several thousand editions.—The 16th century opened with the foundation of the university of Wittenberg (1502), and inaugurated along with the reformation a new era in literature by Luther's translation of the Bible, which he rendered into German so harmonious and beautiful that it is considered even at the present day as a model of terse expression. The High German, as used by Luther, is so pure that all the antiquated and anomalous dialects which had until then alternately predominated in German composition were from that time more or less banished from the language, and the idiom of the Bible has since become the sole medium of cultivated conversation and of German literature. Hymns and psalms were now brought to perfection. That famous religious lyric, *Ein' feste Burg ist unser Gott*, and others of Luther's finest hymns, have become classic, and have found hosts of imitators, the most distinguished of whom were Decius and Speratus, and, in the 17th century, Paul Gerhard. Michael Weiss translated the hymns of Huss into German. The writings of Luther, Zwingli, Johann Arnd, Melancthon, Ulrich von Hutten, Bugenhagen, Bullinger, and other reformers and scholars, constitute the principal theological literature immediately connected with the reformation. In historical works, the influence of the reformation manifested itself in the superior style and greater comprehensiveness of the universal histories of Sebastian Frank and Sebastian Münster; also in chronicles of Switzerland by Tschudi, and of Bavaria by Aventinus. Frank also published a collection of German proverbs; in which branch of literature, however, he was preceded and excelled by Johann Agricola's *Auslegung deutscher Sprüchwörter*. Albrecht Dürer's writings unfolded original views of the fine arts in their connection with mathematical science. The principal events in prose belles-lettres were the translations into German of Latin tales, in which Boccaccio, Poggio, and other Italian novelists and

poets were for the first time introduced to German readers. Translations of Tasso and Ariosto also appeared. Many of the ancient chivalric stories, which had been published in prose in the 15th century, were republished in the 16th; collections of them were made and called *Volksbücher* (books for the people), of which the *Buch der Liebe* ("Book of Love") became the most popular. The period before and after the reformation was especially fruitful in satirical and allegorical works. One of the most remarkable of the former kind was the *Narrenschiff* ("Ship of Fools"), by Sebastian Brant of Strasburg (new ed. by Zarnke, Strasburg, 1854), a metrical satire on the follies of the century, which in the opinion of Hallam may possibly have suggested to Erasmus his *Encomium Morie*. Thomas Murner imitated this in his *Narrenbeschwörung* ("Conjuration of Fools"), and published one of his bitterest satires on Luther under the title *Von dem grossen Lutherischen Narren* ("Of the Great Lutheran Fool"). The fable of *Reineke Fuchs* (afterward immortalized by Goethe's poem), the origin of which is identified by many authorities with the ancient epic or didactic poem of the *Thiarsage*, and which in different periods had appeared in a variety of forms, was revived in a Low German edition (translated from the Dutch) in the latter part of the 15th century, and was looked upon in the 16th as a satire on the government and state of society of Germany. It was followed by a great number of poems of the same kind, of which one whose characters are few is the most witty. Among the purely didactic fabulists were Alberus and Burkard Waldis, both also eminent as composers of hymns. Among the more comic of the *Volksbücher* was the story of *Till Eulenspiegel*, relating the freaks, pranks, drolleries, fortunes, and misfortunes of a wandering jester (new ed. by Lappenberg, 1854). The ablest satirical and didactic poet of the 16th century was Johann Fischart, the author of more than 50 works, including the above mentioned fable on fleas (*Flohstich*), and of a romantic poem (*Das glückhafte Schiff*) which was regarded as a model for romancers. He has been called the German Rabelais. The story of Faust and the autobiography of Götz von Berlichingen, afterward adorned by Goethe, were also among the popular works of this century. The *Volkslieder* or popular songs of this period were much admired by Herder, who was the first to collect them. The *Meistersänger*, upon whom the mantle of the minstrels had fallen since the 14th century, had established metrical schools in various German towns, in the same spirit in which they would have founded guilds of trade. Their highest ideal of poetry was conformity to the rules of versification which were adopted by their school committees. In the 16th century their corporation derived great prestige from the genius of Hans Sachs, the poet and cobbler of Nuremberg (then the headquarters of the

*Meistersänger*), whom Herder calls the *Meister* of *Meistersinger*, and who excelled more than any poet before him in all styles of composition, from the most tragical touch of feeling to the most comic turn of thought. His song dedicated to Luther (*Wittenbergische Nachtigall*) was especially fine. Frauenlob and Michael Behaim were also poets, and Rosenblüt and Folz playwrights of some note, the former of whom was also one of the best tale writers of his time. Among the contributors to the drama who succeeded Hans Sachs, he was excelled in skilful arrangement of plots by Jakob Ayer (died in 1605), and in grace and refinement of composition by Andreas Gryphius (1616-'64).—During the excitement occasioned by the reformation almost all branches of composition were cultivated, but in learned and scientific literature the 16th century was most prolific. Besides Melancthon, whose influence secured the preponderance of the Aristotelian philosophy in the Protestant schools of Germany for more than a century, were Luther, Camerarius (classics and philology), Cornelius Agrippa, Theophrastus Paracelsus (mystical philosophy and natural history), Copernicus (astronomy), Leonhard Fuchs (botany and medicine), Conrad Gesner (botany, zoölogy, and classics), and Agricola (mineralogy). At the expiration of the 16th century few of the great scholars of Germany were left, and classical culture was declining in the early part of the 17th. The numerous universities and schools which had sprung up under the influence of the reformation were no longer animated by the zeal of the reformers, but engrossed by subtle polemical and scholastic strifes. The deliverance of the German intellect from the scholastic bonds of the middle ages, which was the cherished endeavor of Luther, was again retarded.—Poetry, in passing from the *Meistersänger* to scholars, lost in naturalness what it gained in elaboration. Most aspirants to poetical fame in the 17th century were graduates of universities, and learned societies were formed at its beginning, with a view of improving the German language and literature. These societies became as notorious for their imitations of the Italian academies as the corporations of the *Meistersänger* had been for attempting to mimic the minstrels. After their dissolution they were replaced by many literary and scientific associations in Leipsic, Berlin, Hamburg, Königsberg, Halle, and in others of those principal central and university towns of Protestant Germany which had become the leaders of German culture. A new school of poetry was established, of which the forerunners were Friedrich von Speer (died in 1635) and Georg Rudolf Weckherlin (1584-1651), the first author of sonnets in German. Martin Opitz (1597-1639) became the leader of this school, which after his native country was called the first Silesian school. He wrote the language with a purity of idiom in which he rivalled Luther. He imparted more vigor to the versification, and wrote many lyrical, mixed, and didactic poems. Although more scholastic than poetical, he exerted a great influence on literature, at a time when the thirty years' war and the growing taste for bad Italian and French modes of composition threatened to annihilate all vestiges of pure German poetry, and when the reforms introduced by Luther into the language still required to be steadily urged and followed up in order to become established. Paul Flemming (1609-'40) was the principal lyrical, and Simon Dach (1605-'59) a gifted sentimental poet of this school. Von Zesen (1619-'89) was the greatest purist of them all, strenuously opposing the admixture of French words, which was becoming more and more common in Germany. Halsdörfer was one of the principal poets of the pastoral Nuremberg branch of the school. Among the other eminent poets were Christian Weise, who excelled in popular songs and the drama, and afterward opposed the Silesian schools, and Friedrich von Logau (1604-'55), a witty epigrammatist. Andreas Gryphius did much to improve the German drama, and his poetry was as excessively passionate as that of Opitz was conventional and cold. This conventionality gave rise to a formidable opposition, at the head of which stood Hofmannswaldau (1618-'79) and Lohenstein (1635-'83), who took the most inflated Italian and French writers as their models, and became proverbial for bombast and artificiality. They in their turn were opposed by Canitz, the Berlin statesman and poet (1654-'90), Besser (1654-1729), and König (1688-1744), most of whom were court poets, who endeavored to imitate the then fashionable verses of Boileau, but were unable to resist the success of Lohenstein's affected and extravagant effusions. Imitativeness was the bane of literature in Germany; only a few, as Brookes of Hamburg (1680-1747) and Günther (1695-1723), were free from it, while Neukirch (1665-1729), and especially Wernike of Hamburg (died about 1720), were almost the only poets who dared to protest against it.—The most successful authors of novels in this period were Buchholz, Von Zesen, Ziegler, Klipphausen, Lohenstein, and Duke Anton Ulrich of Brunswick. The most entertaining book of the century was a collection of tales of adventure (*Simplicissimus*) by Grimmelshausen, a style of composition in which he had been preceded by the satirist Moscherosch. The writings of the Roman Catholic preacher Abraham à Sancta Clara (1642-1709) are distinguished by a broad humor, especially his *Judas*. Among the prose writers of the 17th century were S. von Pufendorf in political philosophy, Kepler (who wrote in Latin) in astronomy, and Gottfried Arnold in ecclesiastical history. Among writers on theology and ethics, Spener, the founder of Protestant pietism, takes a prominent position. In philosophy and learning Latin continued to be the sole medium of literature; and Jakob

Boehm (1575-1624), the great mystic, stood for a long time almost alone in the use of the vernacular tongue, until the latter part of the century, when Leibnitz (1646-1716) and Wolf (1679-1754) appeared. Christian Thomasius (1655-1728), the able jurist and pietistic philosopher and writer, was the first, in his lectures at Leipsic and afterward at Halle, to substitute the German for the Latin language as the medium of instruction. He was also among the very first to use the German language in his writings, and established the first German learned periodical in Leipsic (1688-'90). Leibnitz was the first to lay a scientific basis for the study of philosophy in Germany, but his works were chiefly written in Latin and French. Wolf, his disciple, shaped the views of Leibnitz into a comprehensive system, and published his works in the German language.—Under the impulse of the new philosophical ideas, Germany became in the 18th century excited on the subject of literature, as it had been on that of theology in the 16th. The 17th closed with the foundation of the Berlin academy by Leibnitz (1700). The general clamor was for reform in education, in literature, and soon for reform in all departments of thought. Gottsched in Leipsic (1700-1766), laboring in the same direction as Thomasius, exerted himself to make the German language the sole medium of instruction, and published in it manuals and abridgments of philosophy and science. He advocated the classical rules of composition of Racine and Corneille, but aimed above all at correctness. His views brought him into conflict with Bodmer (1698-1783) and Breitinger of Zürich (1701-'76), who were admirers of Milton and rigidly orthodox in religion, while Gottsched was friendly to Voltaire. They carried on a paper war in their respective journals, until at length many who had rallied round Gottsched became disgusted with his pedantry, and separating themselves from him, established a periodical celebrated in German literature under the name of *Bremer Beiträge*, edited by Gärtner (1712-'91), in which they opposed their former friend; at the same time they formed a poetical union to which Hagedorn was friendly, although he did not join it, but which was eventually joined by Klopstock, who became its hero. Among the contributors to this journal were Rabener (1714-'71), a popular satirist, of a correct and easy style; Zachariä (1726-'77), a writer of poetry in imitation of Pope's "Rape of the Lock;" Gellert (1715-'69), a famous fabulist; Kästner, the poet and mathematician; Giseke; Johann Elias Schlegel, dramatist, and Johann Adolph Schlegel (1721-'93), poet; Fuchs, Cramer, Ebert, translator of Young's "Night Thoughts," and several others. The journal was printed in Bremen, but the poets resided for some time at Leipsic, whence they adopted the name of the second Saxon school, while the followers of Bodmer (of Zürich) styled themselves the Swiss school.

Related to the latter was the school of Halle to which belonged Lange, Pyra, Uz, and Götze. The most distinguished of the poets of this school were Kleist (1715-'59), author of descriptive and picturesque poetry in the manner of Thomson and Pope, and Ramler (1723-'98), a composer of odes, and the first to introduce the language, versification, and manner of the ancients into Germany. Gleim (1719-1803), the celebrated fabulist and poet, at first a follower of Bodmer, gathered a knot of writers around him, and exercised for about 40 years a considerable influence on German poetry; but his fame was diminished by the criticisms of Herder. Salomon Gessner of Zürich (1730-'87) gained in his time a high reputation as a writer of idylls, but Herder thinks that he was overrated by his contemporaries. Bodmer's prestige was also soon broken by the criticisms of Lessing. Of greater influence than any of the poets as yet named were Hagedorn of Hamburg (1708-'54), whose fables and songs have immortalized him in Germany, and Albert von Haller (1708-'77), the illustrious physiologist and savant, who was remarkable as a writer of descriptive and didactic poetry. They were followed by Klopstock (1724-1803), whose "Messiah" made a profound impression upon the religious world by its mystic, devout, and rapturous faith, while as a work of art it was greatly admired. The fashionable and elegant portion of society was attracted by the semi-Grecian, semi-Parisian muse of Wieland (1733-1813). But it was reserved for Lessing (1729-'81) to give a new direction to German literature. He did for what Luther had done for the German language. He established a new school of criticism, and struck a final blow at Gallic influence, at the same time that Frederick the Great was coquetting with the French graces. His tragedy *Emilia Galotti*, his comedy *Misanthropie*, and his philosophical drama *Nathan der Weise*, are models of dramatic composition. He exerted a powerful influence on the progress of the German drama by unfolding for the first time all the beauty, vigor, and originality of Shakespeare before the German mind, and by the profound and philosophical criticisms in his *Dramaturgie*. He pronounced a condemnatory judgment upon all foreign models except Shakespeare and the ancients, and demonstrated that the spirit of the age shrank from the mediæval sentimentality of epic poetry, and desired literature to reflect its own stirring energies, as the drama alone can do. Most celebrated among the many literary publications which were identified with Lessing's critical labors was a periodical (*Literaturbriefe*) which he founded in Berlin in 1759, in conjunction with Nicolai (1733-1811), the publisher and author. Lessing was the master spirit of this publication, and the principal contributor next to himself was his friend Moses Mendelssohn (1729-'86). Both Klopstock and Wieland were criticised in that peri-

odical, and it was the first to discover the merit of Winckelmann the archæologist, of Hamann the mystic philosopher, and the philosophical genius of Kant, although at that time he had only written some short treatises. Shortly after the commencement of the *Literaturbriefe*, a new influence was infused into the literary world by Herder (1744-1803), who while at Königsberg became acquainted with Hamann and Kant, and who was known as a scholar as early as 1762. He brought to bear upon literature an almost universal knowledge, the study of the poets of all nations, an intimate acquaintance with Hebrew, Greek, and Latin writings, and above all a cosmopolitan humanitarian spirit, which, together with his poetical genius, manifested itself most suggestively in the crowning work of his life, *Ideen zur Philosophie der Geschichte der Menschheit*. He contributed powerfully to promote the study of oriental poetry, and was the first to call attention to the beauty of the ancient popular songs of different nations, and particularly of his own. Another great impulse was given by Winckelmann (1717-'68). His examinations of the remains of ancient art and his writings modified all the old theories of the beautiful; and by his efforts, combined with those of Lessing, whose celebrated work *Laokoon* was elicited by Winckelmann's suggestions, the spirit of art and poetry was brought back to the genuine and simple taste of the Greeks. Heyne, the accomplished critic and commentator, propounded the theories of Winckelmann at Göttingen, then the most brilliant university of Germany. The young men there became deeply impressed with the new theories, and, under the influence of the reforms which were then initiated in religion, philosophy, literature, art, and education—in almost all departments of thought and life—founded in 1770 the *Musenalmannach*, a literary journal, and not long afterward a poetical union known as the *Göttinger Dichterbund*, or *Hainbund*. Klopstock became the leader and model of these enthusiastic youths, whose aim was to give a new stimulus to poetic emulation, and to oppose to conventional theories a school of poetry founded upon the inspirations of genius and humanity. Among the members of the union were Bürger (1748-'94), the author of *Lenore* and other wild and picturesque ballads and songs; Voss (1751-1826), one of the most learned and eloquent philologists of his day, immortalized by his translations of Homer and Virgil, and the author of one of the best German idyls (*Luise*); Hölty (1748-1776), whose songs became exceedingly popular; the two Stolbergs, who cooperated with Voss in familiarizing the Germans with the ancients, and who excelled in various kinds of metrical composition; Clandius, Müller, Hahn, Cramer, Götter, and Boje. A genial poet of this period was Pfeffel (1736-1809), whom it would be difficult to class with any particular school. Goethe (1749-1832), already known to fame, and ac-

quainted with Herder and other poets, but keeping himself aloof from all unions and parties, came forward in 1773 with *Gotz von Berlichingen*, which was greeted as the commencement of an entirely new period in German dramatic literature. In 1774 appeared *Werther's Leiden*. The reformatory period of literature was now over. The revolution had set in, or the *Sturm- und Drangperiode*, as it was called after a drama of that name by Klinger (1753-1831), whose high-wrought tragedies and novels, as well as the writings of Schubart (1739-'91), Heinse (died in 1803), Lenz (1750-'92), and Müller (1750-1825), reflect most forcibly the excitement of this epoch. In the mean time Schiller (1759-1805) produced his *Räuber*, followed by *Fiesco* and *Cabale und Liebe*. These impassioned tragedies gave a new impetus to the literary excitement. His *Don Carlos*, however (1784), shows greater moderation, and opens a long series of tragedies in which the highest aspirations for liberty and humanity are interwoven with historical associations, expressed in language of the most classical purity. But it was only after Schiller's union with Goethe (1795) that by their combined labors German literature was brought to that classical perfection which, from a purely national, has since given to it a universal influence. Schiller, by his enthusiastic and sympathetic eloquence and tenderness, became the favorite of the people; and Goethe, with his many-sided intellect and boundless sensibilities, controlled by a strong will, encased in a body of exuberant health, and disciplined by an all-embracing culture and knowledge, became the acknowledged sovereign of German literature.—While this golden era of letters was in a great measure accelerated by the philosophic spirit of the age which had prompted the labors of Lessing and the other reformers, that spirit itself gathered strength from the light which it diffused, and in rapid succession gave birth to Kant (1724-1804), Fichte (1762-1814), Hegel (1770-1831), and Schelling (1775-1854). Lessing, especially by his comprehensive essay on the "Education of the Human Race," Herder, Moses Mendelssohn, and Hamann are philosophical writers of great eminence. In a popular style wrote Engel, the author of *Lorenz Stark*, and the psychological novels of Jacobi are among the most suggestive of German prose writings. Among other prose writers are Reinhold and Barth; Alexander Gottlieb Baumgarten, generally considered the founder of the science of aesthetics (in Latin); Meier, the German interpreter of his theories; and Sulzer, who wrote on the same science. Abbt, Garve, Liscow, the philosopher and elegant fabulist, Lavater the physiognomist, his friend Zimmermann, and his sarcastic and polished opponent Lichtenberg; the historians Dohm, Möser, Schröckh, Schlözer, and Beck; Spittler, the celebrated Göttingen historian; Mosheim, the ecclesiastical historian; Johannes von Müller, the his-

Oct. 30, was based entirely on the right of conquest, the question of the lawful succession in the duchies and the claims of the federal diet being ignored. When Prussia after the conclusion of peace called upon Hanover and Saxony to withdraw their troops from Holstein, Saxony showed some intention to resist by force. A collision was averted by a resolution of the federal diet, which in accordance with the demand of Austria and Prussia declared the execution to be ended. The disagreement between Austria and Prussia now began to widen. Austria desired to have the administration of the duchies transferred to Prince Frederick of Augustenburg; Bismarck entered into negotiations concerning the annexation of the duchies to Prussia. The federal diet took an unavailing interest in the cause of Prince Frederick, and finally confined itself to a protest against the illegal solution of the Schleswig-Holstein question, while the crown jurists of Prussia undertook to prove that Christian IX. of Denmark was the lawful duke of Schleswig-Holstein, which therefore, in virtue of the peace of Vienna, belonged to Austria and Prussia. A better understanding between Austria and Prussia appeared to be established when the latter power, in April, 1865, concluded a commercial treaty with the Zollverein. On Aug. 14 the Gastein convention gave Austria the exclusive occupation of Holstein, to Prussia that of Schleswig, and annexed Lauenburg to Prussia. The resolution of another general assembly of deputies of all the German states, which was held at Frankfort in October, and which demanded the convocation of the diet of Schleswig-Holstein, was entirely disregarded by the two great powers. Soon a new difficulty sprang up between Austria and Prussia. The permission given by the Austrian governor of Holstein, Gen. von Gablenz, to hold an anti-Prussian meeting at Altona, Jan. 23, 1866, led to a very angry exchange of diplomatic notes. Austria warned the other states against the ambitious schemes of Prussia in a circular note of March 16, and began to arm. As the states of the second rank did not conceal their entire sympathy with Austria, Prussia in April strengthened her position by an alliance with Italy, and also began to arm. At the same time Prussia made a bid for the sympathy of the masses of the people in the smaller states by moving in the federal diet, on April 9, the convocation of a general national assembly, to be elected by direct and universal suffrage. An understanding arrived at between Prussia and Austria to begin the disarmament on April 25 and 26 failed, as Austria refused to withdraw her army from the Italian frontiers. A peace congress, proposed by England, France, and Russia, likewise failed, because Austria demanded the exclusion of all negotiations concerning the extension of the territory of either disputant. On June 1 Austria transferred the decision of the Schleswig-Holstein question to

the federal diet. This was regarded by Prussia as a termination of the Gastein convention; her troops were at once marched into Holstein, and the Austrian governor of Holstein was invited to reënter into the joint occupation of Schleswig. Austria denounced this act as a violation of the federal constitution, and on June 14 the federal diet, by a majority of 3 against 6, adopted the view of Austria and ordered the mobilization of the entire federal army, except the troops of Prussia. The states voting for this resolution were Austria, Bavaria, Saxony, Hanover, Würtemberg, Hesse-Cassel, Hesse-Darmstadt, Nassau, and the small states forming the 16th class. The representative of Prussia at once declared that the majority of the federal diet had exceeded its authority, and that Prussia regarded the confederation as dissolved. On the following day, the governments of Hanover, Saxony, and Hesse-Cassel were requested by Prussia to take back their vote of the preceding day, to disarm, and to enter into a new confederation with Prussia, which in that case would guarantee their sovereignty; in case of refusal, the immediate opening of hostilities was announced. The three governments on the same day refused this demand, and on June 16 their territory was occupied by Prussian troops. The brilliant campaign of the Prussians (see PRUSSIA) against the Austrians, who had been joined by the Saxon troops, in Bohemia and (June 23 to July 22), and against the federal troops in Thuringia and in the valley of the Main (June 27 to the beginning of August), completed the dissolution of the confederation and secured the reconstruction of Germany on an entirely new basis. The preliminary peace of Nikolsburg, July 26, confirmed by the definitive peace of Prague, Aug. 23, excluded Austria from Germany, provided for the establishment of a new confederation of the states N. of the Main, Bavaria, Baden, and Hesse-Darmstadt, were liberty to establish a South German confederation including Schleswig-Holstein, Hanover, Hesse, Nassau, and Frankfort were incorporated into Prussia. Even before the conclusion of the definitive peace Prussia had formed offensive and defensive alliances with Saxony (Aug. 18), Baden (Aug. 17), and Hesse-Darmstadt (Aug. 22). On Aug. 24 the representatives of the old German confederation from Frankfort had removed, and the work of the old diet was at an end. The North German Confederation (*Norddeutscher Bund*) was established by ties between Prussia and the other states during the period from Aug. 1866 to Dec. 1871. On Dec. 15 an assembly of plenipotentiaries met in Berlin to draft the constitution of the confederation, which was referred to the constituent National Assembly, which met in Erfurt, and on April 16 adopted by

votes the draft submitted to it. The king of Prussia, as president of the confederation, appointed Bismarck federal chancellor, and on July 1 the constitution went into operation. In February the South German states had held military conferences in Stuttgart to promote a greater conformity of their army organization with that of Prussia. Baden favored the adoption of the entire Prussian system; and when the other three states declined to go so far, though they admitted the desirability of greater uniformity, Baden concluded a special military convention with Prussia. Next to the adoption of the federal constitution, the most important event in the constituent Reichstag was an interpellation of Herr von Bennigsen, one of the leaders of the liberal party, concerning the right of Prussia to garrison the federal fortress of Luxemburg. The grand duchy of Luxemburg, which formed a part of the old German confederation, showed the most decided opposition to entering the new North German, and Prussia had given her consent for the grand duchy to remain outside of the reconstructed Germany. Soon after negotiations had been begun between France and Holland for a sale of the grand duchy to France, Prussia had entered an emphatic protest against this scheme, and on March 30 the king of Holland had officially denied any intention to sell Luxemburg. The full details of these negotiations only became known officially in consequence of the interpellation of Bennigsen, and created an extraordinary excitement throughout Germany. The expression of public opinion against the transfer of Luxemburg to France was no less decided in the south of Germany than in the north. The grand duchy of Hesse concluded in April a military convention with Prussia, in virtue of which its military system was reorganized according to the Prussian, and the Hessian troops were placed under the chief command of the king. Württemberg also introduced several features of the Prussian system. No doubt could be entertained that, in case of war, northern Germany might safely rely on the support of all the South German states. But a conference of the powers which had signed the London treaty of 1839 found a peaceable solution for the Luxemburg question. The grand duchy was declared neutral territory under the guarantee of all the powers represented at the conference; and the federal fortress was to be razed. This peaceable solution was hastened by the declaration of Bismarck that if the result of the conference should not be favorable to the preservation of peace, he would at once mobilize 900,000 men. On May 28 the ministers of the South German states were invited by Prussia to come to Berlin in order to put the Zollverein's treaty on a safe basis. An agreement was arrived at, according to which, for the legislation on affairs of the Zollverein, the South German states would send a specified number of members to the North German fed-

eral council, and order the election of a proportional number of deputies, who in union with the North German Reichstag would constitute the customs parliament. A new attempt of Napoleon to meddle in the progress of German reconstruction by demanding that, in accordance with one article of the treaty of Prague, the people of northern Schleswig be allowed to express by a plébiscite their preference for Denmark or Germany, was sharply repelled by Prussia, Bismarck declaring that Prussia was unwilling to recognize the right of France to watch over the fulfilment of the treaty of Prague. An interview of Napoleon with the emperor of Austria in August was looked upon as a threatening movement against Germany, and not only the North German states, but even the Germans of Austria, strongly expressed themselves against the endeavors of France to interfere in any way in the internal affairs of the German nation. In the grand duchy of Hesse, the second chamber demanded that the entire grand duchy, instead of only the northern portion as hitherto, be admitted into the North German confederation. In Baden both the government and the chambers expressed a wish to enter the confederation. Bismarck issued a circular note on the demonstrations of public opinion, which he declared to be significant proofs that the national feeling of the Germans would never brook a foreign interference in German affairs, and would never allow the development of the affairs of the German nation to be guided by any other considerations than the national interests of Germany. But while South Germany gave no encouragement to the schemes of Napoleon against the progress of German unity, there remained a widespread dissatisfaction with the policy of Prussia, and an unwillingness to tighten the bonds of union. At the election for the first German customs parliament, the South German party, which opposed any advances toward a closer union, elected 50 out of 89 South German deputies. Even in the grand duchy of Baden it met with an unexpected success. When, in reply to the opening speech of the king of Prussia, the national liberal party moved an address which asked for an enlargement of the functions of the customs parliament, and distinctly hinted at the complete union of north and south, the ultra-conservative feudal party of Prussian deputies, the radical party of progress (*Fortschrittspartei*), the Catholic party, and the socialists united with the South German party and caused its rejection by 186 against 150 votes. The conciliatory but firm attitude of the Prussian government prevented the progress of the centrifugal sentiments in South Germany. The governments of Bavaria and Württemberg, although disinclined to make further concessions on the union question, were on the other hand no less unflinching in the observance of the treaties which regulated their relation to northern Germany. Baden,

on May 25, 1869, concluded a new military convention with Prussia, which established an entire uniformity between the armies of Baden and Prussia. The North German Reichstag expressed a decided opinion in favor of restricting the right of particular states and enlarging the functions of the central authorities. The first six months of the year 1870 were unusually quiet, and it was the common opinion that great changes in the relation of the four South German states to the North German confederation were not likely to be made for a long time to come, when suddenly the action of France precipitated the final solution of the German question. The Spanish crown having been offered to Prince Leopold of Hohenzollern, and rejected, the emperor Napoleon demanded the guarantee of Prussia against its acceptance at any time thereafter by any prince of its house. This being scornfully refused, war was at once declared by France (July 19, 1870), and, after a brilliant series of victories for the Germans and almost uninterrupted defeats for the French, was in effect concluded by the preliminary peace of Versailles, Feb. 26, 1871. (See FRANCE.) In this war all the states both of North and South Germany, except Austria, participated; and in view of the common danger through which all had passed, and the common victory which all had won, the governments and the people of South Germany now waived any further opposition to a consolidation of all the German states under the leadership of Prussia. On Nov. 15, 1870, a treaty was concluded between the North German confederation, Baden, and Hesse concerning the establishment of the German confederation (*Deutscher Bund*); on Nov. 23 the entrance of Bavaria into the confederation was regulated by treaty; on Nov. 25, that of Württemberg. Bavaria asked and received important concessions, which to many unionists appeared to be going too far in favor of particularism; but the treaty was unanimously ratified by the federal council of the North German confederation, and by the Reichstag by 195 against 32 votes. On Dec. 3 the king of Bavaria invited the king of Prussia to restore the dignity of German emperor; most of the other governments gave their assent to the proposition before Dec. 8. In the name of the federal council the federal chancellor on Dec. 9 moved in the Reichstag, and the motion was adopted on the following day, that the German confederation assume the name German empire, and the king of Prussia, as president of the confederation, the title emperor of Germany. On Jan. 18, 1871, the restoration of the imperial dignity was solemnly proclaimed by the king of Prussia at Versailles; on March 21 the first German Reichstag assembled at Berlin, and was opened by the emperor in person. On April 14 this Reichstag ratified the constitution of the German empire, with but three dissenting votes; and on May 4 the constitution went into

operation. By the peace of Versailles Germany recovered the province of Alsace and the German-speaking district of Lorraine. The definitive peace was concluded at Frankfurt on May 10, and on June 9 the new *Reichsland* of Alsace-Lorraine was proclaimed as incorporated with Germany. The majority of the Reichstag, in full harmony with the imperial government and the majority of the federal council, was intent upon consolidating the new empire by centralizing the legislation and extending the functions of the central authorities. As two German states, the grand duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz, were still without a constitutional government, the Reichstag on Nov. 8 adopted the resolution of the deputy Büsing that every German state must in future have a constitutional form of government. On Nov. 15, on motion of Lasker, it was resolved to embrace the whole of the civil law within the sphere of the imperial legislation. Of the political parties which opposed the advancing consolidation of the empire, by far the most powerful was the Catholic, or the centre, as it was called from the central seats which its representatives occupied in the Reichstag. (See also) At the opening of the first session of the Reichstag in March, 1871, they moved an amendment to the address by which the Reichstag replied to the speech from the throne, for the protection of the temporal power of the pope. On this question the Catholics united against them almost unanimously. The address moved by the majority of the Reichstag was adopted by 243 votes, the minority consisting of the Catholics and a few socialists. The opposition between them and the imperial government became more intense in 1872. One of the chief causes of speech which the pope had made was regarded by the majority of the Reichstag as a direct wish for the overthrow of the German empire, and intensified the sore feeling which had been produced by the pope's refusal to recognize the German government. The cardinal prince Hohenlohe, who had been appointed to the papal court, was of opinion that the religious intolerance in the Catholic districts was entirely due to the influence of the pope on the Reichstag and federal council. He moved a law which provided for the suppression of all the houses of the Jesuit orders. This law, which was passed in the year 1872, was generally regarded as defining which other religious orders were comprehended within its terms. The Lazarists, ladies of the order, and others shared at once the fate of the Jesuits. The bishops of Germany met in a general council at Bonn, and bitterly complained of the law against the pope, in an allocution which was published in terms still more severe than those of the anti-Catholic

the imperial government of Germany replied by breaking off all diplomatic intercourse with the papal court. Thus the relation between the Catholic church and the imperial government at the beginning of 1873 was one of open war. This was particularly the case in the kingdom of Prussia, where the relation between church and state was regulated by a number of new laws which all the bishops positively refused to obey. The government then imposed heavy fines upon the bishops, and in many cases withdrew the support which the ministers and institutions of the church had received from the state government. An interesting correspondence on the subject took place between the pope and the emperor. The pope expressed the hope that the cruel laws against the church did not meet the approbation of the emperor, and asked for his personal interference in behalf of the church; to which the emperor replied that in a constitutional state like Prussia every law required the sanction of the sovereign, and that the former peace between the different Christian churches had been wantonly disturbed by the unlawful conduct of the bishops. A germ of new difficulties between the state governments and the Catholic church was the legal position claimed by the Old Catholics, who maintained that the pope and the bishops who adhered to the decree of the Vatican council had abandoned the Catholic church, and that they alone were entitled to be regarded as the true representatives of that Catholic church which in Germany until 1870 was regarded as one of the state churches. Although the state governments, in view of the comparatively small number of the Old Catholics, declined to accept their view of the ecclesiastical situation, they at the same time refused to treat them as seceders from the Catholic church, and took the ground that the movement was an internal affair of that church, with which the state had no right to meddle. In Prussia, the missionary bishop of the Old Catholics was accordingly recognized in October, 1873, as a bishop of the Catholic church, and as such he at once received a salary from the state. The political changes in France greatly encouraged the hopes of the Catholic opposition in Germany, and in several southern districts of Bavaria led to threatening demonstrations against the very existence of the German empire. As a similar effect was produced by the political attitude of the French government in Italy, the visit of the king of Italy to Berlin was enthusiastically hailed by the liberal parties, both in Italy and in Germany, as an indication that the two governments intended to act in full concert against the common enemy. The relations between the governments of the smaller states and the emperor up to the close of 1873 were friendly, and no serious discrepancy of opinions on any important subject was shown in the deliberations of the federal council. — Among the best historical works on Germany are K. A. Meuzel's *Ge-*

*schichte der Deutschen* (8 vols., 1815-'22), and *Neuere Geschichte der Deutschen* (12 vols., 1826-'48); Luden's *Geschichte des deutschen Volkes* (to the 13th century, 12 vols., 1829-'39); and Giesebrecht's *Geschichte der deutschen Kaiserzeit* (vols. i.-iii., 3d ed., 1862-'8).

**GERMANY, Language and Literature of.** The formation, the history, and the philological affinities of the German tongue have been treated at length in the article GERMANIC RACES AND LANGUAGES, and we shall therefore restrict our remarks in this article to a brief sketch of the modern High German language as now spoken and written. In this the five vowels, *a*, *e*, *i* (*y*), *o*, and *u*, sound as in Italian, the sound being lengthened by doubling the vowels: *ā* (or *ae*), when long, is like *a* in *mate*, when short almost like *e* in *met*; *ō* (*oe*), long, is like but somewhat duller than the French *eu* in *feu*, when short it resembles the English *u* in *tub*; *ū* (*ue*) is also duller than the French *u* in *sur* and *ture*. *C* before *e* and *i* (*y*), and *z* always, stands for *tz* or *ts*, as in English *petz*; *ck* for *kk*, as in English *peck*, *suck*; *g* is always hard, generally as in *get*, *gire*, but sometimes almost like German *ch*, as in *ewig*, *weg*; *h* before a vowel has the same sound as in our *has*, *hen*; *ch* is harsher than *h*, and like the Greek *χ* or the Spanish *jota*; *j* sounds like *y* in *yes*; *r* is always whirring; *r*, in German words, has the sound of *r*, and in foreign of the English *r*; *w* sounds like English *r*. *S* has a threefold sound: 1, like the Latin *s*, in the combination *st*, at the end of a syllable, as *fest*, *Fürst*, and in forms derived therefrom, *festst*, *Fürsten*, &c., at the end of words, as in *das*, *gutes*, &c., and when double, as in *nass*, *Wasser*, &c.; 2, much like the English *z*, at the beginning of words, before vowels, and between vowels, as in *Sonne*, *dicke*, &c.; 3, like the English *sh* in *shell*, at the beginning of words before some consonants, as *Scandal* (Latin), *spit*, *still*, &c., though in a part of Germany it is pronounced like the English *s* in *sa*. *Sch* is like the English *sh* in *shell*. *Sz* stands for *ss* after long vowels or at the end of words, and is thus written also in derivative forms, as *mausz* and *misz* from *maessen*. *ai* is pronounced like the English *ay* (*yes*); *au* like *ou* in *our*; *ei* (or *ey*) like *i* in *mine*. *Eu* has a very peculiar sound, approaching the English *oi*, and *au* is somewhat heavier. *E*, the weakest sound, is most frequently employed: 1, for filling up the transition between consonants, thus, *er liebet* for *liebt* (the latter form is now more common); hence it is often elided, as *nah'n* for *nahen*, as in English *power* for *power*, *hear'n* for *hearken*; 2, for lengthening *i* when that letter precedes it, as in *wieder*, again, distinguishing it from *weider*, against, counter; 3, as a mark of the plural, as *Steine*, stones, from *Stein*. *H*, the weakest consonant, is also used for lengthening a preceding vowel, as in *schr*, *wohl*, &c. Besides *e*, three dentals and three liquids serve for all grammatical inflections. They are *d*, *s*, *t*, and *m*, *n*, *r*; *s*, *m*,

*n*, *r* are employed with nouns, *d*, *s*, *t*, *n* with verbs. The following is a synopsis of all grammatical endings attached to words: nominative (of the definite article) *der*, *die*, *das*, plural *die* for all genders; genit. *des*, *der*, *des*, plur. *der*; dat. *dem*, *der*, *dem*, plur. *den*; accus. *den*, *die*, *das*, plur. *die*. These are the endings of adjectives, nouns, and adjective pronouns. Comparative *dicker*, superl. *dickeſt*; receiving the preceding endings when declined. Endings of substantive nouns: singular genit. *es* or *s*, as *Dorf-es*, or like the nominative; dat. *e*, or like the nominative; plur. *e*, dat. *en*—new declension everywhere *en* or *n* (*des Falcken*, &c.). Some substantives take *r* after *e* in the plural, and undergo metaphony, as in *Bad*, *Bäder*, *Volk*, *Völker*, *Tuch*, *Tücher*. The verbal endings are as follows: 1. Strong verbs (commonly called old conjugation): indicative present, *e*, *est* or *st*, *et* or *t*; plural, *en* or *n*, *et* or *t*, *en* or *n*; past, first and third persons have no ending, second *est*, or *st*; plural, *en*, *et*, *en*; imperative singular, first person wanting, second and third *e*; plural, *en*, *et* or *t*, *en*; participle past, prefix *ge*, suffix *en*. 2. Weak verbs (improperly called regular, really inorganic conjugation) have the same terminations as the preceding, except in the past tense, where *et* or *t* is inserted between the stem and the ending; participle past, prefix *ge*, suffix *et* or *t*. In both the ending of the participle present is *end*, infinitive *en*. The subjunctive of both has the endings always preceded by *e*, and the past of the strong verbs undergoes metaphony, as *ich gab*, I gave; *ich gäbe*, I might give. The strong verbs, whose conjugation is called irregular, exhibit the phonetic vicissitudes of words, and are therefore to be regarded as organic and containing the rules of the language; while the so-called regular verbs are weak, undergo no change, and only admit of mechanical additions.—All words of Teutonic physiognomy have the accent on the radical syllable; those taken from or resembling French, generally on the last effective syllable; and those from other languages on that syllable which to the German ear seems to be the radical; thus: *Empfindlichkeit*, sensibility; *unzuerlässlich*, untrustworthy, &c.; but *Regiment*, *Solidarität*, *Kapitän*, &c. The German language has in a very high degree three qualities which render it both very plastic in its material and very flexible in its adaptability to all forms and categories of thought. These qualities are: 1, intuitiveness of expression, owing to the organic etyma of the Indo-European family of languages, which are clearest in the Latin (see LANGUAGE); 2, facility of composition of simple words into double or manifold agglomerates, requiring long paraphrases in other languages; 3, power of polysyllabic derivatives from radical words. These latter qualities do not impair the first.—Among the most eminent of the founders of German philology are Benecke, J. and W. Grimm, and Lachmann. See J. Grimm, *Deutsche Gramma-*

*tik*, comprising also the Scandinavian b (Göttingen, 1819-'37); Hoffmann von Fallenberg, *Deutsche Philologie im Grundriss* (Leipzig, 1836), with a bibliography of dialects, *Denkmäler der deutschen Sprache* (Berlin, 1838-'51); Wackernagel, *Deutsche Sprachgeschichte* (3 vols., Basel, 1839-'48); J. Grimm, *Geschichte der deutschen Sprache* (Leipzig, 1846). For grammars of new High German, see Elmsläder (about 1525); Albertus (1573); Gerhart, *Unterricht der hochdeutschen Sprache* (1574); Clajus, *Grammatica Germanica* (1578); Martin Opitz, on German poetry (1624); Schottel, *Deutsche Sprachkunst* (1641); Morhof, *Unterricht von der deutschen Sprache und Poesie* (1682); Bödiker, *Grundsätze der deutschen Sprache* (1690); Heynatz (1770); Basedow (1775); Bodmer (1775); Fulda, *Grundregeln der deutschen Sprache* (1778); Adelung (1778); Heinsius (1798); J. Ch. A. Heyse (1814); F. Becker (1829). For dictionaries, see F. Beck, *Deutsch-lateinisches Wörterbuch* (1741); Adelung (1774-'86); Moritz, *Grammatisches Wörterbuch der deutschen Sprache* (1793); C. F. W. Müller, *Versuche deutscher Sprachbereicherung* (1794), and *Wörterbuch zur Aufklärung und Verdeutschung der unserer Sprache entlehnten fremden Ausdrücke* (1801); Brandt, 1807-'13); Heyse, *Allgemeines Wörterbuch zur Verdeutschung*, &c. (1804); Heinsius, *Volksthümliches Wörterbuch* (1812); Adler, *German and English* (New York, 1814); K. W. L. Heyse (1833-'49); J. Grimm, a gigantic work, begun half a century ago and not yet completed. On style, see Gottsched, *Beobachtungen über den Geschmack und Missbrauch vieler deutscher Wörter* (1705); Eberhard (1710); Wiegand, Ch. F. Meyer, &c.—The German literature received its first impulse from the fondness of the early Germans for the legends in song the fabulous and heroic of their traditions and history. The legends immediately connected with Gothic and Burgundian warriors of the 5th and 6th centuries, the national migration were eventually embodied in the lay of the *Nibelungen*, the production of German medieval literature. The spirit of the *Nibelungen* is romantic and mythological. Christianity manifested itself as early as the 8th century in the translation of the Bible (probably by Bishop Liudger) of which remain, and are the oldest German literature, as the earliest in the Gothic language. The Carolingian emperors established Christianity in Germany between the 8th and 9th centuries and laid the foundation of the national structure which in the 10th century was perfected by Charlemagne. The production of the Gospels appears in the old High and Low German of the former (*Krist*, new ed.,

and the latter (*Heliand*, first published in Munich, 1830-'40) preserving the ancient alliterations. A translation of the Psalms by Notker, which dates from about the same period, is regarded as one of the best specimens of old High German literature. The *Ludwigslied*, a pæan in honor of the victory of the Frankish king Louis III. over the Normans about 880, which Herder extols as one of the best specimens of early German poetry, was composed in the old High German dialect by a Frankish churchman. The preservation of the song of Hildebrand, which is associated with the legends of Theodoric and Attila, is also due to churchmen, who transmitted it partly in the old High German and partly in the Low German dialect. Several Latin poems were also based upon Hunnish and Burgundian legends, but with these exceptions the priesthood were generally opposed to the national poetry on account of its pagan associations. Many Latin chroniclers and poets flourished in this and the following period; there was also a Latin poetess, Roswitha, or Helena von Rossow, who wrote Latin religious plays. The learning which flourished under the Saxon emperors was superior to that of the times of Charlemagne. The study of mathematics was next in importance to that of theology and Latin. The Greek language, although it was but little cultivated, was not unknown. From the 10th to the 13th century Germany probably possessed a higher mental cultivation than any other country in Europe, but on the whole it was of a Latin and ecclesiastical cast, and the people had no share in it. In the 12th century appeared a hymn in praise of Hanno, archbishop of Cologne, which Herder calls a truly Pindaric song. Among the last poems which appeared in this era from the pen of churchmen were the *Rolandlied* and the *Alexanderlied*.—In the 12th century poetry passed from the monasteries and ecclesiastical schools to the palaces of princes and the castles of nobles. Most of the poets who then came forward were nobles by birth, some of them princes. Heinrich von Veldeke was the first to introduce into his heroic poem *Enit*, which he is said to have composed after a French version of Virgil, the spirit of devotion to woman, or *Minne* (an old German word for love, whence the name *Minnesänger*). Veldeke is regarded as the originator of the heroic minstrel song, although he is far surpassed in genius, elevation of thought, and depth of feeling by Wolfram von Eschenbach. The other masters of the heroic muse were Gottfried of Strasburg, Hartmann von der Aue, and Konrad of Würzburg. Their longer heroic poems treat chiefly of the exploits of Charlemagne and of the story of Arthur and the round table. At the same time they composed many songs. Love was their principal theme, but from a sense of delicacy the name of the lady who was the special object of adoration was never mentioned. Respect for womanhood, which was reckoned among the virtues of the ancient

Germans even in the days of the deepest barbarism, contributed to make the German love songs more reverential than those of the French troubadours. A species peculiar to the bards was called the watch song, consisting in a dialogue between a lover and the sentinel who guards his mistress. Walther von der Vogelweide was the most gifted of these lyric poets. Next to him rank Heinrich von Ofterdingen, Reimar der Alte, Heinrich von Morungen, Gottfried von Neifen, and the Austrian bards Nithard and Tanhäuser. Several hundred of these poets were engaged in wandering from palace to palace and from castle to castle. The minstrels constituted what is called the Swabian school of poetry; the songs were mostly in the Swabian dialect. The accession of the Swabian emperors of the house of Hohenstaufen to the throne of Germany was the signal for the rise of the bardic art (1138). Its golden age was shortly before the fall of that dynasty (1254). The crowning event of the minstrel era was the appearance of the lay of the *Nibelungen*. It was followed by the "Book of Heroes" (*Heldenbuch*), consisting of a collection of fragmentary pieces treating of the same legends as the *Nibelungen*, but mixed up with traditions of the crusades.—Didactic poetry began to be cultivated with some success in the 13th century. The dawn of historical works is heralded by several local chronicles; that of writings on natural history in the so-called *Meininger Naturlehre*; of popular religious literature in the sermons of David of Augsburg and Berthold of Winterthur; and of works on jurisprudence in compilations of Saxon and Swabian laws (*Sachsenspiegel* and *Schwabenspiegel*). Ulrich von Lichtenstein deploras, in 1275, in his famous poem on *Frauentrost* (devotion to woman), the decline of chivalry, but his attempt to revive its spirit was hopeless. Poetry now passed from the abodes of princes and knights to the homes of burghers and the workshops of artisans; and instead of *Minnesänger* we hear of *Meistersänger*, as the plebeian songsters were called. The 13th century, the greater part of which was so rich in poetical productions, was one of the most unfruitful for the cause of learning. Leibnitz says that the 10th century in Germany was a golden age in that respect compared with the 13th.—In the 14th century Germany possessed several mystic theologians, followers of Meister Eckart, the principal of whom was Johann Tauler (1290–1361), whose sermons and writings contributed to pave the way for the reformation. An important event of this century, in its general influence upon the future development of German literature, was the establishment of the university of Prague in 1348, soon followed by universities in almost all parts of Germany. The last echoes of the period of chivalric poetry were two allegorical romances, *Tuercdanck* in verse, and *Weiskünig* in prose (first published at the beginning of the 16th century), of which the emperor Maxi-

milian is the hero and probably the author, although Melchior Pfünzing is said to have composed the former romance at the emperor's request. The only good poetry of the 14th and 15th centuries was the spirited songs of Halbsuter and Veit Weber, celebrating the victories of Switzerland over Austria and Burgundy.—The progress of classical culture was stimulated at the opening of the 15th century by the establishment of learned societies and schools in different parts of Germany and the Low Countries. Hegius, Langius, Dringeburg, Reuchlin, Agricola, and other eminent men were among the scholars. Purbach was the first restorer of mathematical science, and his pupil Regiomontanus (Johann Müller) was the greatest mathematician of the 15th century; while Gutenberg was one of its heroes. His invention of the art of printing produced a steadily increasing literary activity, and the books printed in Germany between 1470 and 1500 amounted to several thousand editions.—The 16th century opened with the foundation of the university of Wittenberg (1502), and inaugurated along with the reformation a new era in literature by Luther's translation of the Bible, which he rendered into German so harmonious and beautiful that it is considered even at the present day as a model of terse expression. The High German, as used by Luther, is so pure that all the antiquated and anomalous dialects which had until then alternately predominated in German composition were from that time more or less banished from the language, and the idiom of the Bible has since become the sole medium of cultivated conversation and of German literature. Hymns and psalms were now brought to perfection. That famous religious lyric, *Ein feste Burg ist unser Gott*, and others of Luther's finest hymns, have become classic, and have found hosts of imitators, the most distinguished of whom were Decius and Speratus, and, in the 17th century, Paul Gerhard. Michael Weiss translated the hymns of Huss into German. The writings of Luther, Zwingli, Johann Arnd, Melancthon, Ulrich von Hutten, Bugenhagen, Bullinger, and other reformers and scholars, constitute the principal theological literature immediately connected with the reformation. In historical works, the influence of the reformation manifested itself in the superior style and greater comprehensiveness of the universal histories of Sebastian Frank and Sebastian Münster; also in chronicles of Switzerland by Tschudi, and of Bavaria by Aventinus. Frank also published a collection of German proverbs; in which branch of literature, however, he was preceded and excelled by Johann Agricola's *Auslegung deutscher Sprüchwörter*. Albrecht Dürer's writings unfolded original views of the fine arts in their connection with mathematical science. The principal events in prose belles-lettres were the translations into German of Latin tales, in which Boccaccio, Poggio, and other Italian novelists and

poets were for the first time introduced to German readers. Translations of Tasso and Ariosto also appeared. Many of the ancient chivalric stories, which had been published in prose in the 15th century, were republished in the 16th; collections of them were made and called *Volkbücher* (books for the people), of which the *Buch der Liebe* ("Book of Love") became the most popular. The period before and after the reformation was especially fruitful in satirical and allegorical works. One of the most remarkable of the former kind was the *Narrenschiff* ("Ship of Fools"), by Sebastian Brant of Strasburg (new ed. by Zarncke, Strasburg, 1854), a metrical satire on the follies of the century, which in the opinion of Hallam may possibly have suggested to Erasmus his *Encomium Morie*. Thomas Murner imitated this in his *Narrenbeschwörung* ("Conjurament of Fools"), and published one of his bitterest satires on Luther under the title *Von dem grossen Lutherischen Narren* ("Of the Great Lutheran Fool"). The fable of *Reineke Fuchs* (afterward immortalized by Goethe's poem), the origin of which is identified by many authorities with the ancient epic or didactic poem of the *Thiarsage*, and which in different periods had appeared in a variety of forms, was revived in a Low German edition (translated from the Dutch) in the latter part of the 15th century, and was looked upon in the 16th as a satire on the government and state of society of Germany. It was followed by a great number of poems of the same kind, of which one whose characters are few is the most witty. Among the purely didactic fabulists were Alberus and Burkard Waldis, both also eminent as composers of hymns. Among the more comic of the *Volkbücher* was the story of *Till Eulenspiegel*, relating the freaks, pranks, drolleries, fortunes, and misfortunes of a wandering jester (new ed. by Lappenberg, 1854). The ablest satirical and didactic poet of the 16th century was Johann Fischart, the author of more than 50 works, including the above mentioned fable on fleas (*Flöhen*), and of a romantic poem (*Das glückhafte Schiff*) which was regarded as a model for romancers. He has been called the German Rabelais. The story of Faust and the autobiography of Götz von Berlichingen, afterward adorned by Goethe, were also among the popular works of this century. The *Volklieder* or popular songs of this period were much admired by Herder, who was the first to collect them. The *Meistersänger*, upon whom the mantle of the minstrels had fallen since the 14th century, had established metrical schools in various German towns, in the same spirit in which they would have founded guilds of trade. Their highest ideal of poetry was conformity to the rules of versification which were adopted by their school committees. In the 16th century their corporation derived great prestige from the genius of Hans Sachs, the poet and cobbler of Nuremberg (then the headquarters of the

*Meistersänger*), whom Herder calls the *Meister of Meistersänger*, and who excelled more than any poet before him in all styles of composition, from the most tragical touch of feeling to the most comic turn of thought. His song dedicated to Luther (*Wittenbergische Nachtigall*) was especially fine. Frauenlob and Michael Behaim were also poets, and Rosenblüt and Folz playwrights of some note, the former of whom was also one of the best tale writers of his time. Among the contributors to the drama who succeeded Hans Sachs, he was excelled in skilful arrangement of plots by Jakob Ayer (died in 1605), and in grace and refinement of composition by Andreas Gryphius (1616-'64).—During the excitement occasioned by the reformation almost all branches of composition were cultivated, but in learned and scientific literature the 16th century was most prolific. Besides Melancthon, whose influence secured the preponderance of the Aristotelian philosophy in the Protestant schools of Germany for more than a century, were Luther, Camerarius (classics and philology), Cornelius Agrippa, Theophrastus Paracelsus (mystical philosophy and natural history), Copernicus (astronomy), Leonhard Fuchs (botany and medicine), Conrad Gesner (botany, zoölogy, and classics), and Agricola (mineralogy). At the expiration of the 16th century few of the great scholars of Germany were left, and classical culture was declining in the early part of the 17th. The numerous universities and schools which had sprung up under the influence of the reformation were no longer animated by the zeal of the reformers, but engrossed by subtle polemical and scholastic strifes. The deliverance of the German intellect from the scholastic bonds of the middle ages, which was the cherished endeavor of Luther, was again retarded.—Poetry, in passing from the *Meistersänger* to scholars, lost in naturalness what it gained in elaboration. Most aspirants to poetical fame in the 17th century were graduates of universities, and learned societies were formed at its beginning, with a view of improving the German language and literature. These societies became as notorious for their imitations of the Italian academies as the corporations of the *Meistersänger* had been for attempting to mimic the minstrels. After their dissolution they were replaced by many literary and scientific associations in Leipsic, Berlin, Hamburg, Königsberg, Halle, and in others of those principal central and university towns of Protestant Germany which had become the leaders of German culture. A new school of poetry was established, of which the forerunners were Friedrich von Spee (died in 1635) and Georg Rudolf Weckherlin (1584-1651), the first author of sonnets in German. Martin Opitz (1597-1639) became the leader of this school, which after his native country was called the first Silesian school. He wrote the language with a purity of idiom in which he rivalled Luther.

He imparted more vigor to the versification, and wrote many lyrical, mixed, and didactic poems. Although more scholastic than poetical, he exerted a great influence on literature, at a time when the thirty years' war and the growing taste for bad Italian and French modes of composition threatened to annihilate all vestiges of pure German poetry, and when the reforms introduced by Luther into the language still required to be steadily urged and followed up in order to become established. Paul Flemming (1609-'40) was the principal lyrical, and Simon Dach (1605-'59) a gifted sentimental poet of this school. Von Zesen (1619-'89) was the greatest purist of them all, strenuously opposing the admixture of French words, which was becoming more and more common in Germany. Halsdörfer was one of the principal poets of the pastoral Nuremberg branch of the school. Among the other eminent poets were Christian Weise, who excelled in popular songs and the drama, and afterward opposed the Silesian schools, and Friedrich von Logau (1604-'55), a witty epigrammatist. Andreas Gryphius did much to improve the German drama, and his poetry was as excessively passionate as that of Opitz was conventional and cold. This conventionality gave rise to a formidable opposition, at the head of which stood Hofmannswaldau (1618-'79) and Lohenstein (1635-'83), who took the most inflated Italian and French writers as their models, and became proverbial for bombast and artificiality. They in their turn were opposed by Canitz, the Berlin statesman and poet (1654-'90), Besser (1654-1729), and König (1688-1744), most of whom were court poets, who endeavored to imitate the then fashionable verses of Boileau, but were unable to resist the success of Lohenstein's affected and extravagant effusions. Imitativeness was the bane of literature in Germany; only a few, as Brockes of Hamburg (1680-1747) and Günther (1695-1723), were free from it, while Neukirch (1665-1729), and especially Wernike of Hamburg (died about 1720), were almost the only poets who dared to protest against it.—The most successful authors of novels in this period were Buchholz, Von Zesen, Ziegler, Klipphausen, Lohenstein, and Duke Anton Ulrich of Brunswick. The most entertaining book of the century was a collection of tales of adventure (*Simplicissimus*) by Grimmelshausen, a style of composition in which he had been preceded by the satirist Moscherosch. The writings of the Roman Catholic preacher Abraham à Sancta Clara (1642-1709) are distinguished by a broad humor, especially his *Judas*. Among the prose writers of the 17th century were S. von Pufendorf in political philosophy, Kepler (who wrote in Latin) in astronomy, and Gottfried Arnold in ecclesiastical history. Among writers on theology and ethics, Spener, the founder of Protestant pietism, takes a prominent position. In philosophy and learning Latin continued to be the sole medium of literature; and Jakob

Boehm (1575-1624), the great mystic, stood for a long time almost alone in the use of the vernacular tongue, until the latter part of the century, when Leibnitz (1646-1716) and Wolf (1679-1754) appeared. Christian Thomasius (1655-1728), the able jurist and pietistic philosopher and writer, was the first, in his lectures at Leipsic and afterward at Halle, to substitute the German for the Latin language as the medium of instruction. He was also among the very first to use the German language in his writings, and established the first German learned periodical in Leipsic (1688-'90). Leibnitz was the first to lay a scientific basis for the study of philosophy in Germany, but his works were chiefly written in Latin and French. Wolf, his disciple, shaped the views of Leibnitz into a comprehensive system, and published his works in the German language.—Under the impulse of the new philosophical ideas, Germany became in the 18th century excited on the subject of literature, as it had been on that of theology in the 16th. The 17th closed with the foundation of the Berlin academy by Leibnitz (1700). The general clamor was for reform in education, in literature, and soon for reform in all departments of thought. Gottsched in Leipsic (1700-1766), laboring in the same direction as Thomasius, exerted himself to make the German language the sole medium of instruction, and published in it manuals and abridgments of philosophy and science. He advocated the classical rules of composition of Racine and Corneille, but aimed above all at correctness. His views brought him into conflict with Bodmer (1698-1783) and Breitingen of Zürich (1701-'76), who were admirers of Milton and rigidly orthodox in religion, while Gottsched was friendly to Voltaire. They carried on a paper war in their respective journals, until at length many who had rallied round Gottsched became disgusted with his pedantry, and separating themselves from him, established a periodical celebrated in German literature under the name of *Bremer Beiträge*, edited by Gärtner (1712-'91), in which they opposed their former friend; at the same time they formed a poetical union to which Hagedorn was friendly, although he did not join it, but which was eventually joined by Klopstock, who became its hero. Among the contributors to this journal were Rabener (1714-'71), a popular satirist, of a correct and easy style; Zacharia (1726-'77), a writer of poetry in imitation of Pope's "Rape of the Lock"; Gellert (1715-'69), a famous fabulist; Kästner, the poet and mathematician; Gieseke; Johann Elias Schlegel, dramatist, and Johann Adolph Schlegel (1721-'93), poet; Fuchs, Cramer, Ebert, translator of Young's "Night Thoughts," and several others. The journal was printed in Bremen, but the poets resided for some time at Leipsic, whence they adopted the name of the second Saxon school, while the followers of Bodmer (of Zürich) styled themselves the Swiss school.

Related to the latter was the school of Halle to which belonged Lange, Pyra, Uz, and Gitz. The most distinguished of the poets of this school were Kleist (1715-'59), author of descriptive and picturesque poetry in the manner of Thomson and Pope, and Ramler (1723-'98), a composer of odes, and the first to introduce the language, versification, and manners of the ancients into Germany. Gleim (1719-1803), the celebrated fabulist and poet, at first a follower of Bodmer, gathered a knot of writers around him, and exercised for about 40 years a considerable influence on German poetry; but his fame was diminished by the criticisms of Herder. Salomon Gessner of Zürich (1730-'87) gained in his time a high reputation as a writer of idylls, but Herder thinks that he was overrated by his contemporaries. Bodmer's prestige was also soon broken by the criticisms of Lessing. Of greater influence than any of the poets as yet named were Hagedorn of Hamburg (1708-'54), whose fables and songs have immortalized him in Germany, and Albert von Haller (1708-'77), the illustrious physiologist and savant, who was remarkable as a writer of descriptive and didactic poetry. They were followed by Klopstock (1724-1803), whose "Messiah" made a profound impression upon the religious world by its mystic, devout, and rapturous faith, while as a work of art it was greatly admired. The fashionable and elegant portion of society was attracted by the semi-Grecian, semi-Parisian muse of Wieland (1733-1813). But it was reserved for Lessing (1729-'81) to give a new direction to German literature. He did for it what Luther had done for the German language. He established a new school of criticism, and struck a final blow at Gallic influence, at the same time that Frederick the Great was coquetting with the French graces. His tragedy *Emilia Galotti*, his comedy *Misanthrope*, and his philosophical drama *Nathan der Weise*, are models of dramatic composition. He exerted a powerful influence on the progress of the German drama by unfolding for the first time all the beauty, vigor, and originality of Shakespeare before the German mind, and by the profound and philosophical criticisms in his *Dramaturgie*. He pronounced a condemnatory judgment upon all foreign models except Shakespeare and the ancients, and demonstrated that the spirit of the age shrank from the mediæval sentimentality of epic poetry, and desired literature to reflect its own stirring energies, as the drama alone can do. Most celebrated among the many literary publications which were identified with Lessing's critical labors was a periodical (*Literaturbriefe*) which he founded in Berlin in 1759, in conjunction with Nicolai (1733-1811), the publisher and author. Lessing was the master spirit of this publication, and the principal contributor next to himself was his friend Moses Mendelssohn (1729-'86). Both Klopstock and Wieland were criticised in that peri-

odical, and it was the first to discover the merit of Winckelmann the archæologist, of Hamann the mystic philosopher, and the philosophical genius of Kant, although at that time he had only written some short treatises. Shortly after the commencement of the *Literaturbriefe*, a new influence was infused into the literary world by Herder (1744-1803), who while at Königsberg became acquainted with Hamann and Kant, and who was known as a scholar as early as 1762. He brought to bear upon literature an almost universal knowledge, the study of the poets of all nations, an intimate acquaintance with Hebrew, Greek, and Latin writings, and above all a cosmopolitan humanitarian spirit, which, together with his poetical genius, manifested itself most suggestively in the crowning work of his life, *Ideen zur Philosophie der Geschichte der Menschheit*. He contributed powerfully to promote the study of oriental poetry, and was the first to call attention to the beauty of the ancient popular songs of different nations, and particularly of his own. Another great impulse was given by Winckelmann (1717-'68). His examinations of the remains of ancient art and his writings modified all the old theories of the beautiful; and by his efforts, combined with those of Lessing, whose celebrated work *Laokoon* was elicited by Winckelmann's suggestions, the spirit of art and poetry was brought back to the genuine and simple taste of the Greeks. Heyne, the accomplished critic and commentator, propounded the theories of Winckelmann at Göttingen, then the most brilliant university of Germany. The young men there became deeply impressed with the new theories, and, under the influence of the reforms which were then initiated in religion, philosophy, literature, art, and education—in almost all departments of thought and life—founded in 1770 the *Musenalmannach*, a literary journal, and not long afterward a poetical union known as the *Göttinger Dichterbund*, or *Hainbund*. Klopstock became the leader and model of these enthusiastic youths, whose aim was to give a new stimulus to poetic emulation, and to oppose to conventional theories a school of poetry founded upon the inspirations of genius and humanity. Among the members of the union were Bürger (1748-'94), the author of *Lenore* and other wild and picturesque ballads and songs; Voss (1751-1826), one of the most learned and eloquent philologists of his day, immortalized by his translations of Homer and Virgil, and the author of one of the best German idyls (*Luise*); Höltz (1748-1776), whose songs became exceedingly popular; the two Stolbergs, who cooperated with Voss in familiarizing the Germans with the ancients, and who excelled in various kinds of metrical composition; Claudius, Miller, Hahn, Cramer, Götter, and Boje. A genial poet of this period was Pfeffel (1736-1809), whom it would be difficult to class with any particular school. Goethe (1749-1832), already known to fame, and ac-

quainted with Herder and other poets, but keeping himself aloof from all unions and parties, came forward in 1773 with *Gotz von Berlichingen*, which was greeted as the commencement of an entirely new period in German dramatic literature. In 1774 appeared *Werther's Leiden*. The reformatory period of literature was now over. The revolution had set in, or the *Sturm- und Drangperiode*, as it was called after a drama of that name by Klinger (1753-1831), whose high-wrought tragedies and novels, as well as the writings of Schubarth (1739-'91), Heinse (died in 1803), Lenz (1750-'92), and Müller (1750-1825), reflect most forcibly the excitement of this epoch. In the mean time Schiller (1759-1805) produced his *Räuber*, followed by *Fiesco* and *Cabale und Liebe*. These impassioned tragedies gave a new impetus to the literary excitement. His *Don Carlos*, however (1784), shows greater moderation, and opens a long series of tragedies in which the highest aspirations for liberty and humanity are interwoven with historical associations, expressed in language of the most classical purity. But it was only after Schiller's union with Goethe (1795) that by their combined labors German literature was brought to that classical perfection which, from a purely national, has since given to it a universal influence. Schiller, by his enthusiastic and sympathetic eloquence and tenderness, became the favorite of the people; and Goethe, with his many-sided intellect and boundless sensibilities, controlled by a strong will, encased in a body of exuberant health, and disciplined by an all-embracing culture and knowledge, became the acknowledged sovereign of German literature. - While this golden era of letters was in a great measure accelerated by the philosophic spirit of the age which had prompted the labors of Lessing and the other reformers, that spirit itself gathered strength from the light which it diffused, and in rapid succession gave birth to Kant (1724-1804), Fichte (1762-1814), Hegel (1770-1831), and Schelling (1775-1854). Lessing, especially by his comprehensive essay on the "Education of the Human Race," Herder, Moses Mendelssohn, and Hamann are philosophical writers of great eminence. In a popular style wrote Engel, the author of *Lorenz Stark*, and the psychological novels of Jacobi are among the most suggestive of German prose writings. Among other prose writers are Reinhold and Barth; Alexander Gottlieb Baumgarten, generally considered the founder of the science of aesthetics (in Latin); Meier, the German interpreter of his theories; and Sulzer, who wrote on the same science. Abbt, Garve, Liscow, the philosopher and elegant fabulist, Lavater the physiognomist, his friend Zimmermann, and his sarcastic and polished opponent Lichtenberg; the historians Dohm, Möser, Schröckh, Schlözer, and Beck; Spittler, the celebrated Göttingen historian; Mosheim, the ecclesiastical historian; Johannes von Müller, the his-

edition of the *Nibelungen*, did much to promote a love for the study of the old German dialects and the poetry connected with them. The brothers Wilhelm and Jakob Grimm are the more immediate founders of this new branch of philological and poetical investigation. Benecke, Lachmann, and Simrock labored in the same direction, and more recently Moritz Haupt; also Franz Pfeiffer, Oskar Schade, Zarneke, Holtzmann, Hoffmann von Fallersleben, Bartsch, &c.—The German war of independence against Napoleon I. produced some striking patriotic songs from Prof. Arndt of Bonn (1769–1860), and Theodor Körner (1791–1813), the gallant soldier-poet, and author of *Leier und Schwert* ("Lyre and Sword"). Some of the lyrical poets of the romantic school whom we have named also became distinguished for their patriotic effusions, especially Schenkendorf and Stagemann. Wilhelm Müller of Dessau (1794–1827), author of the admirable *Griechenlieder*, may be classed among patriotic poets. The maiden efforts of Friedrich Rückert (1789–1866), one of the best lyrical and didactic poets of Germany, and celebrated as much for his imitations of troubadour songs as for his versions of oriental poetry, were also inspired by the war against the French. Another who came forward as a champion of national independence was Uhland (1787–1862), the chieftain of the modern Swabian school, and one of the leading poets of Germany. Stuttgart, the seat of the great publishing house of Cotta and of the critic Wolfgang Menzel, was the headquarters of this school. Hebel (1760–1826), whose *Alemannische Gedichte* were greatly admired by Goethe, belonged to it by the Swabian dialect and spirit of his songs, although he lived at an earlier period. An eminent lyrical poet of this school was Justinus Kerner. Gustav Schwab, Pfizer, the critic and historian, Karl Mayer, and Mörike, all belong more or less to the Swabian school. A new direction was given to literary activity by the political excitement immediately preceding and succeeding the French revolution of 1830. Ludwig Börne (1786–1837) and Heinrich Heine (1800–1856) are regarded as its heralds, the former by his pungent and comprehensive political satires, the latter by his keen insight and peculiar lyrical genius. Heine exercised a wide influence in the literary world. As a poet, he had a peculiar gift of uniting the tragic and comic in a felicitous and racy manner, which made him the idol of a new school of authors who styled themselves "Young Germany," but who partook much less of Heine's poetical gifts than of his political sympathies. Karl Gutzkow (born in 1811) was the head of this school. He is the author of *Die Ritter vom Geiste* and *Zauberer von Rom*, and of many other novels, and several dramas. The other principal representatives of "Young Germany" are Heinrich Laube (born in 1806), Gustav Kühne (1806), and Theodor Mundt (1808). An emi-

nent author of this period is Baron Sternberg (1806), author of *Diane* and *Paul*, and of many other works which hold up the mirror to the social and political condition of his country. Another famous writer and amateur liberal politician of this class is Prince Pückler-Muskau (1785–1871), author of *Briefe eines Verstorbenen*, and of other piquant books. The taste for novels of a political and social tendency has been characteristic of German writers since the early part of this century. The novels of Gutzkow, Laube, and many other contemporary German writers, all belong to this category, while Gustav Freytag has gained a high reputation by several excellent novels, among which the best known is *Soll und Haben* ("Debit and Credit"). The line of historical novelists was opened by Meissner (1753–1807); he was followed by Karoline von Pichler (1769–1843), Tromlitz (Von Witzleben, 1773–1839), Van der Velde (1779–1824), Karl Spindler (1796–1855), author of *Der Jude*, *Der Bastard*, and other novels, which enjoyed great popularity; Rellstab, Storch, Rau, and Koenig (1790–1869), author of *Die Clubisten in Mainz* (1847). Berneck or Bernd von Guseck (born in 1803), Mügge (1806–'61), author of *Toussaint* and other excellent novels, Kühne and Heller (1813–'71), are all contributors to this class of novels. Here belong also the semi-historical novels of Louise Mühlbach (Mme. Mundt, 1814–'73), which have enjoyed a very wide popularity, but are not entitled to high rank either from a literary point of view or as interpreters of history. A far higher merit must be awarded to Zschokke (1771–1848), one of the best German prose writers of recent times, author of many excellent historical and romantic works, and of *Stunden der Andacht*, a religious work, which has passed through many editions. Heinrich Steffens, the Norwegian philosopher and naturalist (1773–1845), wrote German novels based upon Scandinavian history, which are replete with interest. Another historical novelist is Wilhelm Häring, known by the pseudonyme of Wilibald Alexis (1797–1871), who imitated so skilfully the manner and style of Sir Walter Scott that several of his works were translated into foreign languages and passed for some time as the productions of the great English romancer. The most famous of the kind is "Walladmor." Hauff, a genial novelist, whose *Lichtenstein* takes high rank among historical romances; Clauren, a licentious writer, but one whose novels have been read extensively; and Hackländer, the author of *Soldatenleben*, *Handel und Wandel*, and many other works, and the founder and conductor of the widely known journal *Ueber Land und Meer*, may be mentioned here; also Berthold Auerbach (1812), who attracted immediate attention by his first work, *Schwarzwälder Dorfgeschichten*, and has since taken his place among the leaders of German fiction, his novel *Auf der Höhe* having gained a very wide reputation in Germany,

England, and America, which has been increased by his later works. Among German novelists of the last decade whose works possess permanent value, the leading place is undoubtedly occupied by Friedrich Spielhagen, whose *Problematische Naturen*, *Durch Nacht zum Licht*, *Hammer und Amboss*, and other works, enjoy a great popularity and high esteem. Heinrich Laube, Alfred Meissner (a grandson of the historical novelist), Max Ring, Edmund Hoeser, Fanny Lewald, Levin Schücking, Karl von Holtei, and others, have been prolific contributors to the recent literature of fiction. Eugenie John, best known under the *nom de plume* of E. Marlitt, has written several excellent novels, among which *Goldelse* (1866), *Das Geheimniss der alten Mamsell* (1867), and *Reichsgräfin Gisela* (1869) have been exceptionally popular, and have been translated into English. Paul Heyse is another contemporary novelist whose works have attained and deserved much success.—Among the poets who have expressed liberal political tendencies with most point are Hoffmann von Fallersleben, the author of *Unpolitische Lieder*; Herwegh, author of *Gedichte eines Lebendigen*; Dingelstedt, author of *Lieder eines kosmopolitischen Nachtwächters*; Prutz (born in 1810), Kinkel (1815), and Freiligrath. Among other recent poets who have acquired some eminence are Grabbe, Gottschall, Emanuel Geibel, Redwitz, Paul Heyse, Wolfgang Müller, Max Waldau, Gerokt, Bodenstedt (especially distinguished for his versions of Persian poetry), Böttger, Simrock, Kugler, Keller, Schefer, and Hammer, many of whom excel in ballads and songs after the style of the Swabian school. A circle of poets in Vienna cluster round Anastasius Grün (Count Auersperg), the greatest lyric poet of Austria, author of *Spaziergänge eines Wiener Poeten*, *Schutt*, *Der letzte Ritter*, &c. Lenau and Karl Beck were the principal and most gifted of his followers. Alfred Meissner and Moritz Hartmann belong to this school. A few other names of writers who have acquired a passing reputation by attractive or melodious verses might be added here; but during the past decade no really great poet, whose fame is likely to be lasting, has appeared in Germany. The war against France in 1870 called forth, it is true, many national and martial lyrics, among the best of which were several by Freiligrath and Geibel, as well as some stirring songs by the newer writers Gottschall, Grosse, Rittershaus, and Jensen. Several of those named in the list of recent poets given above also produced noteworthy war lyrics. *Die Wacht am Rhein*, written long before (about 1840) by Schneckenburger, became the popular war song of the armies of 1870; but its literary worth was small compared with many others of the national poems published during the period of its popularity.—Dramatic literature has also fallen from the high estate which it had reached through Lessing, Goethe, and Schiller. Gerstenberg (1737–1823) was the author of the

high-wrought tragedy *Ugolino*, noticeable for its extravagance. Among his contemporaries were some excellent dramatic poets, as Cronegk, Leisewitz, Weise, &c. land (1759–1814), in a long series of plays reflected the life of respectable people of the middle classes; they are eminently moral in tone, but long and heavy. Werner (1768–) became the founder of the so-called *schicksalstragödie* by his piece called *Vierundzwanzigste Februar*. The imitators of his extravagant style are Müllner (1774–) in his *Schuld*, Howald (1778–1845) in his *Alte*, and Grillparzer (1790–1872) in his *Alte*. Kotzebue (1761–1819) succeeded in attaining a higher popularity than all his contemporaries. His forte was in comedy. He wrote more than 200 plays, some of which have been adapted to the English and French stage. Münch-Bellinghausen (*nom de plume*, F. Halm) has written an excellent drama, *Sohn der Wildnis*, a national tragedy, *Fechter von Ravenna*, and other works. Eichendorff, Julius Mosen, Gutzkow, Heibel, Griepenkerl, Prutz, and Erckmann have all cultivated dramatic literature. Lotte Birch-Pfeifer (1800–'68) dramatized a great number of stories. Karl Immermann belongs to a higher class of dramatists; his *Alxys*, and his mythical play *Merlin*, and some of his tragedies and comedies, are excellent reading plays, but they are not well adapted to the stage. M. Beer's *Struensee* is also a play of high poetical merit. Raupach (1774–) was one of the most fertile of German dramatists. Eduard Duller (1809–'53) wrote historical dramas. The comedies of Landau, and particularly of Benedix, show considerable ability; and among the writers of comedy are Feldmann, Töpfer, Kow, Gustav Freytag, and Baumbach. Heyse, Wilhelm Jordan, Krüger, Weilen, Wilbrandt, Gustav von Mevius, and Schaffert are among the more recent dramatists. A large number of works are many of positive excellence, but none for which it is possible to predict enduring fame.—Belles-lettres, on the other hand, have in recent years fallen into a state of insignificance in Germany. The minds no longer devote themselves to the study of and dramatic literature, but to the cultivation of the spheres of science and history. Alexander von Humboldt (1769–1859) gave a powerful impulse to almost all departments of knowledge by his "Cosmos," "Views of Nature," and the fruitfulness of his labors. While the 19th century epoch in the pursuit of the sciences was another great movement was the historical researches by Niebuhr, an illustrious historian of ancient Rome (1776–1861), the vigorous and independent of universal history, and the history of the 11th century (1842), the investiga-

with political and commercial relations; Raumer (1781-1878), the historian of the Hohenstaufen; Leopold von Ranke (1793), whose labors embrace a vast field of modern history; Dahlmann (1785-1860), the German Guizot, author of "Sources of German History," and the historian of Denmark and of the English and French revolutions; and Gervinus (1805-'71), the historian of German literature, Shakespearean critic, and author of the great history of the 19th century. Here may be mentioned also Rotteck (1775-1840), whose excellent universal history has been very popular on account of its liberal political views, and Weber, the author of several universal histories. While Niebuhr introduced a profounder method in the study of early Roman history, Bunsen, Lepsius, and others made discoveries in Egyptian and oriental antiquities, and a third impulse proceeded from the active researches in the field of classical archæology and philology. These combined influences are more or less manifest in the labors in ancient history of Böckh, Karl Otfried Müller, Duncker, Droysen, Mommsen, Kortüm, Adolph Schmidt, Plass, Wachsmuth, Tittmann, Flathe, Manso, Abeken, Schwegler, E. Curtius, Lassen, Jahn, Hermann, Teuffel, and Movers. In the special study of Sanskrit Roth, Böhtlingk, Benfey, Fick, A. Weber, and others have won distinction. The history of the middle ages has been treated by Rühls, Rehm, and Wilken, and more especially by Leo, Hammer, Fallmerayer, Aschbach, Lappenberg, Dahlmann, Schäfer, Röpell, Kriegk, and Gregorovius. Various branches of oriental history and literature have been actively explored by Joseph von Hammer-Purgstall, Flügel, Plath, Radloff, Ewald, and Nöldeke. Among writers on modern history are Dohm, Saalfeld, Bülow, Münnich, Häusser, and Treitschke. The humanitarian and cosmopolitan direction given to historical studies by the writers and philosophers of the 18th and 19th centuries, and especially by Herder and Kant, is manifest in the comprehensiveness of views which Rotteck, and chiefly Schlosser, bring to bear upon their labors, as well as in many works on particular sections and occupations of the people. This has culminated in what may be designated as a new science, which the Germans call *Culturgeschichte*, i. e., a history which treats of the moral, intellectual, social, and politico-economical, as well as political development of the people. Among the principal laborers in this new sphere of investigation are Wachsmuth (1784-1866), author of *Europäische Sittengeschichte* and of *Allgemeine Culturgeschichte*; Scherr, author of *Geschichte deutscher Cultur und Sitte*; Klemm (1802-'69), author of *Allgemeine Culturgeschichte der Menschheit*, and of *Allgemeine Culturwissenschaft*; and Henne-am-Rhyn, author of *Culturgeschichte der neueren Zeit*. The same tendency to dwell upon the practical realities of life extends over many other departments of literature in Germany, and is most strongly expressed in recent

biographies and autobiographies, especially in that of Pertheu. A more physiological method in these branches of investigation has been adopted by Riehl in his *Naturgeschichte des Volks als Grundlage einer deutschen Socialpolitik*. The literature of travels was greatly stimulated by Johann Georg Adam Forster, commonly called Georg Forster (1754-'94), who accompanied Cook on his second voyage round the world, and who, in Alexander von Humboldt's opinion, inaugurated a new era of scientific voyages. A still more powerful impulse was given by Humboldt himself, by his travels in the equinoctial regions of America, and in central Asia. The travels of Lichtenstein (1780-1857) in southern Africa were of great scientific importance. The travels of Prince Maximilian of Wied (1782-1867) furnished valuable additions to the knowledge of the natural history and ethnology of Brazil and the United States. The explorations of Martius (1794-1868) in Brazil are important for the studies of botany, ethnology, geography, and statistics. Pöppig (1797-1868) visited Chili, Peru, and the river Amazon. Among the other explorers of South America are Burmeister (born 1807), who travelled more particularly in Brazil, and Johann Jakob von Tschudi (1818), a relative of Friedrich von Tschudi, author of *Das Thierleben in der Alpenwelt*, and an active traveller, especially in Peru. Sir Robert Hermann Schomburgk (1804-'65), a German by birth, but employed in the service of the British government, travelled in British Guiana, Barbadoes, Hayti, &c. His works were published in German by his brother, Otto Schomburgk (1810-'57). Another brother, Moritz Richard Schomburgk, travelled in British Guiana at the expense of the king of Prussia, and afterward in Australia in company with a fourth brother, Julius Schomburgk. The East has been visited by G. H. von Schubert (1780-1860), especially Egypt, Palestine, and Greece, and by Seetzen (1767-1811), whose *Reisen durch Syrien, Palästina, die Trans-Jordan-Länder, Arabia Petrea und Unterägypten*, were edited by F. Kruse. Minutoli (1772-1846) wrote on his travels to Upper Egypt. Rüppell (born 1794) explored Nubia, Kordofan, Arabia Petrea, and is best known by his travels in Abyssinia. The most eminent writers on Egypt are Lepsius, Brugsch, Baron Bunsen, Ebers, Dümichen, and Lauth. The historian Raumer gave graphic descriptions of his travels in Venice, England, Italy, and the United States; and Joseph Russegger (1802-'63) wrote comprehensively on his travels in Europe, Asia, and Africa. Venedey (1805-'71) gave accounts of England, Ireland, and southern France. Moritz Wagner (born 1818) has published his travels in Algeria, the Caucasus, Colchia, Persia, and Kurdistan, and, in conjunction with his companion Scherzer, in North America and Costa Rica. Froebel (born 1806) has described "Seven Years' Travels in Central America, Northern Mexico, and

the Far West of the United States" (English edition, 1859). Hettner (born 1821) has written sketches of his travels in Greece. Friedrich Gerstäcker (1816-'72) is the author of many entertaining and humorous descriptions of travels, especially in the new world. Another pleasing narrator of his journeys is Mundt. A voluminous writer of travels is the tourist Kohl (born 1808). Ida Pfeiffer (1797-1858) showed herself a most intrepid and indefatigable tourist and valuable contributor to the literature of travel. Germany has also given birth to some of the most celebrated recent explorers of remote parts of the world, as Gützlaff in China, Siebold in Japan, Barth, Vogel, Nachtigall, Gerhard Rohlfs, and Heuglin in Africa, the brothers Schlagintweit in central Asia, Bastian in S. E. Asia, and Leichhardt in Australia.—We complete this sketch by a list of eminent men (mostly living) in the principal departments of learning, including some names already mentioned. In the natural sciences: Burmeister, Ule, Johann Müller, Carus, Rossmässler, Dove, Giebel, Masius, Valentin, Moleschott, Büchner, Vogt, Oken, Virchow, Burdach, Schleiden, Bernhard Cotta, Nees von Esenbeck, Leopold von Buch, Endlicher, Martius, Naumann, Bischoff, Liebig, Bunsen, Kirchhoff, Kopp, Poggendorff, Rose, Erdmann, Gmelin, Wöhler, Wackenroder, Gehler, Vogel, Mitscherlich, Pringsheim, Schödlér, Du Bois-Reymond, Fechner, O. Schmidt, F. Cohn, Reichenbach, Unger, Weber, Mohl, Steinheil, Rau, Pietschmann, Reich, Hagen, Lang, Karl, Schrauf, Wundt, H. Grassmann, Hallier, Kummer, Mann, Hartung, Gegenbaur, Fürbinger, Hoffmann, S. Hartmann, Haeckel, Völker, RameLOW, Kupffer, Winkler, Kunth, Fitzinger, Emmerling, Fresenius, Wagner, Meissner, Vom Rath, Baumgärtner, Erdmann, Hofmann, Karmarsch, Würtz, Zwick, Otto, Reis, Robert Grassmann, Zirkel, G. Hartwig, Credner, Pfaff. In medicine: Johann Müller, K. Thiersch, Burdach, Wagner, Ehrenberg, Hecker, Carus, Blasius, Froriep, Schönlein, Skoda, Dieffenbach, Mitscherlich, Romberg, Weber, Donders, A. von Gräfe, Virchow, Steinthal, Reich, W. Roth, Busch, Haussmann, Armbrrecht, Klebs, Nothnagel, Schröder, Steinbacher, Kunze, Fürst, Stilling. In astronomy and mathematics: Bessel, Encke, Struve, Mädler, Galle, Gauss, Lejeune-Dirichlet, Argelander, Heis, Schmidt, Dienger, Förster, Schuchert, Göbel, Osterdinger, Zöllner, Greiffenstein, K. S. Neumann, Möbius, Weisbach, H. J. Klein, Volger, Bischof. In military science, engineering, &c.: Möwes, Taubert, Rebhann, Hagen, Dittmer, Schmitt, Winkler, Lieber, Zastrow. In geography, ethnology, statistics, and travels: Carl Ritter, Daniel, Wappäus, Ungewitter, Berghaus, Petermann, Möller, Stein, Streit, Handtke, Löher, Raumer, Haxthausen, Dieterici, Hübner, Sydow, Möllhausen, Mauch, Munzinger, Hügel, Roon, Schweinfurth, Semper, Seemann, Ziegler, Waitz, Schmarda, Blau, Berlepsch, Pauli, Stieler, Fritsch, Stephan, Stangl, Rodenberg, Stein-

thal, Cornelius, Langhans, Hartmann. In history and biography: Wachler, Gfrörer, Pütz, Leo, K. A. Menzel, Preuss, Weber, Prutz, Varnhagen von Ense, Pertz, K. W. Böttiger, Zimmermann, Von Rochau, G. Curtius, Dittmer, Spiegel, S. Bauer, Fessler, Wolff, Just, Zenz, Grätz, Stockmar, Honegger, Grotefend, Stahl, Elze, Ungewitter, Hagenbach, K. Mendelssohn-Bartholdy, Caspari, Kolb, Holtzendorff, Ukert, Rosenkranz, Brandes, Gentz, Nitzsch, Hirsch, Stoffel, F. Arndt, W. Müller, Wackernagel, Sybel, Kohlrausch, Caro. In the history and criticism of literature, philosophy, art, and aesthetics: Gervinus, Vilmar, Wackernagel, Julian Schmidt, Solger, Bouterwek, Vischer, Schweigler, Ruge, Wolf, Koberstein, Gottschall, Stern, Schell, Kreyssig, Kurz, Lindau, Carrière, Eye, Stahr, Hauptmann, Elze, Meissner, Klein, Gervais, Ethé, Wagner, Zimmermann, Hirsch, J. W. O. Richter, Löper, Schasler, Weiss, Lenz, Liszt, J. P. Richter, Lübke, Fechner, J. H. Schmidt, H. Grimm, Eggers, Lütke, Vogler. In philology: F. A. Wolf, Schaff, Marner, Heinsius, Heyse, K. F. Becker, Massmann, Wilhelm von Humboldt, Zumpt, Hermann, Niebuhr, Bernhardt, Creuzer, Wachler, Con. Schneider, Ernesti, E. and G. Curtius, Matthis, Thiersch, Jacobs, Buttmann, Rost, Pauer, Kühner, Ramshorn, Döderlein, Freund, Gerhard, Gesenius, Nork, Bopp, Freytag, Jahn, Hitzig, Hupfeld, Ewald, A. F. Hoffmann, Lassen, Sachs, L. Geiger, Steinschneider, Levy, Tischendorf, Wattenbach, Lepsius, Schrade, Teuffel, Westermann, Meineke, Leo Meyer, Kremer, Obermüller, Dietz, Brambach, E. H. Arndt, Wollheim da Fonseca, Delitzsch, Holtzmann, Rödiger, Stark, Westphal, Holtzmann, Fick, Schleicher, Schott, Cuno, Zenker, Döderf, J. Müller, Roth, Bensley, Hildebrand, Grassmann, Quenstedt. In political science and jurisprudence: Savigny, Stahl, K. F. Eichhorn, Gans, Hallmann, Welcker, Stein, Bülow, Mohl, Gentz, V. Dove, Holtzendorff, Gneist, Schli, Barth, Glaser, Gerber, Marr, Adler, Oppenhoff, Mohl, Perthes, Schwarz, Richthofen. In the Biblical sciences: Fessler, Rothe, Hefele, Ketteler, Dölner, Guericke, Schenkel, Schleiermacher, Roh, Potlitzsch, B. Banr, F. C. L. kens, Leonhardi, Schulte, von Hartmann, Frol, Zeising, Nietzsche, Uebermacher, Balzer, Lange, Friedberg, Menzel, Kirel, Geiger, Frankel, Hirsch, Luz, Baumann, Winer, T. der, Ludwig Feuerbach, von Hartmann. In the history of science: Diesterweg, Fricke, Schlosser, ker, Schmelzer, L. W. Westermann, Möb

**GERMANY, Wines of.** The wine-producing area of Germany is limited chiefly to those parts watered by the Rhine and its tributaries, the Moselle, the Nahe, the Neckar, the Main, and several smaller streams, so that the terms Rhine wine and German wine may be considered almost synonymous. Bonn, in Rhenish Prussia, and Freiburg, in Baden, mark approximately the northern and southern limits of the grape culture. Both red and white wines are produced, but those known to commerce are, with a few exceptions, white. The red varieties are mostly of inferior quality and are consumed within the country. All are distinguished by their comparative freedom from alcohol, which barely exceeds 12 per cent., and at the same time by their durability, the finer growths frequently retaining their excellence for half a century or more. Liebig attributes their distinctive character and bouquet to the free acid which they contain, and their valuable hygienic properties to the tartar present in them. To this cause he ascribes the immunity enjoyed by persons dwelling on the Rhine and the Moselle, and indeed by all who use German wines, from calcareous complaints. The most favored and celebrated viticultural district in Rhineland is that known as the Rheingau, a strip of territory about 15 m. in length, and not exceeding 3 m. in width, lying between the Taunus range of mountains, in Nassau, and the right bank of the Rhine. It extends from Walluf, just below Mentz, to Lorch, 6 m. below Bingen. The river, after following a northerly course for many miles, turns abruptly at Mentz to the west, in which direction it flows as far as Bingen, when it again turns northward. Having thus a southerly exposure, and being protected from the north winds by the mountains behind it, and from the southwest winds by a range on the west bank of the Nahe, with the further advantage of having the rays of the sun reflected from the river directly upon its slopes, the Rheingau affords a site for vineyards unequalled perhaps in Europe, and has a climate peculiarly favorable to the production of the fragrant and delicate wines for which the district is famous. In connection with the Rheingau may be considered the neighboring district of Hochheim, on the north bank of the Main, about 4 m. from Mentz, and from the first syllable of which is derived the name, hock, by which all Rhenish wines were once designated in Great Britain and the United States. The vineyards of Hochheim have a southerly exposure, and are essentially an easterly continuation of those of the Rheingau. The vine appears to have been cultivated throughout this whole region as early as the 6th or 7th century, but to the monastic foundations established there during the middle ages belongs the credit of discovering and perpetuating the system of viticulture which has brought its wines to their present high degree of perfection. During the religious and civil conflicts which disturbed

Germany from the 16th century to the end of the Napoleonic wars, the most famous vineyards gradually passed from the hands of the monks to those of the dukes of Nassau, the princes of Metternich, or less distinguished proprietors. In the latter half of the last century many new vineyards were planted by persons of means from Mentz, Frankfort, and other neighboring cities; and by the conjunction of capital with intelligent labor the Rheingau has become the most highly cultivated wine-growing region, perhaps, in the world. Within a comparatively recent period the discovery has been made that the Riesling grape, which yields the bouquetted wines, develops its finest qualities only when in a state of over-ripeness, without concurrent acetification. This has led to a complete reform in the treatment of the wines in the cellar. While formerly young wine required from ten to twenty years to ripen, it is now perfected in from three to five years, with a perceptible improvement in quality. In like manner the large casks previously used, to diminish to the utmost the loss by diffusion and evaporation, have been discarded, as they were found to be impediments to the quick maturation of wine by diminishing the surface accessible to oxygen. The vineyards of Hochheim lie about three quarters of a mile from the banks of the Main, above which they are elevated 100 ft., and embrace an area of between 700 and 800 acres. The finest wine is produced on the estate known as the Dechanei, or deanery, eight acres in extent, which has an admirable exposure. The Stein, a continuation of the Dechanei, yields wines which are sometimes said to surpass the best products of the Rheingau. These vineyards, formerly the property of the dukes of Nassau, now belong to the emperor of Germany.—Entering the Rheingau proper, we find a famous series of vineyards extending from the village of Elfeld to Asmannshausen. In the centre of the district, on a gentle eminence half a mile from the Rhine, lies the estate, about 46 acres in extent, of Schloss Johannisberg, a name long associated with the choicest products of the Rhenish vines. It yields a white wine, which in respect to fulness of taste and richness of bouquet has been called “the finest and most powerful drink on earth.” Johannisberg was originally a Benedictine abbey, founded in 1106, which, after various changes of ownership, became in 1815 the property of the emperor of Austria, who bestowed it upon Prince Metternich, with whose descendant it now remains. Notwithstanding the limited area of the estate, the soil varies considerably in different parts, which are marked off by stakes with numbers affixed; and the cultivation and the vintage are especially adapted to each part. A similar practice prevails in other celebrated vineyards of the Rheingau. Great care is exercised in the selection of grapes for the press, the first picking, or *Ausslese*, of over-ripe fruit yielding the highest quality of the

*Pfingstrosen* (4th ed., 1870) and *Palmblätter* (17th ed., 1871), have made him famous. Besides his poems *Blumen und Sternen* (3d ed., 1870), he published during the Franco-German war of 1870-'71 patriotic effusions under the title of *Deutsche Ostern*.

**GÉRÔME, Jean Léon**, a French painter, born in Vesoul, May 11, 1824. In 1841 he went to Paris and studied under Paul Delaroche, whom he accompanied to Italy. He returned to Paris in 1845, and exhibited his first picture in 1847. For several years afterward he travelled in the East, his journeys furnishing him with numerous subjects for pictures. He obtained medals in 1847, 1848, and 1855, and in the last year received the decoration of the legion of honor. In 1863 he became professor of painting in the school of fine arts, and in 1869 was decorated with the order of the red eagle. He has produced many pictures of the life of the ancients, which have placed him at the head of a school of art designated as the Pompeian or New Greek; and several of his pictures have been criticised as indelicate to the last degree. Among his works are "The Virgin, the Infant Jesus, and St. John," "Bacchus and Cupid," "A Greek Interior," the frieze of the vase commemorative of the London exhibition of 1851, "The Plague at Marseilles," "The Death of St. Jerome," and "A Lioness meeting a Jaguar." His masterpiece in historical art is "The Age of Augustus and the Birth of Jesus Christ," exhibited in 1855, and purchased by the French government. He exhibited in London in 1871 a naked Nubian girl, entitled "To be Sold," and "Cleopatra brought to Cæsar in a Basket," the latter inferior to most of his other works. One of his latest pictures, "The Gladiators," was purchased in 1873, by Mr. A. T. Stewart of New York, for 80,000 francs.

**GERONA.** I. A province of Spain, in Catalonia, forming the N. E. extremity of the peninsula, bordering on France and the Mediterranean, and on the provinces of Barcelona and Lérida; area, 2,272 sq. m.; pop. in 1870 (estimated), 325,110. The surface is chiefly covered with the ramifications of the Pyrenees, but fertile valleys frequently intervene. The inhabitants of the interior are mostly engaged in agriculture and cattle rearing; those of the coast in ship building, fishing, and navigation. The principal rivers are the Ter and the Fluvià. Among the towns are Rosas and Figueras, both fortified, Olot, and Ripoll. II. A city (anc. *Gerunda*), capital of the province, at the confluence of the Ter and Oña, 52 m. N. E. of Barcelona; pop. about 10,000. The chief manufactures are linen and woollen fabrics, paper, soap, earthenware, and hardware. It was captured by Charlemagne, regained by the Moors, and is famous for the sieges it has sustained.

**GERRY, Elbridge**, an American statesman, fifth vice president of the United States, born in Marblehead, Mass., July 17, 1744, died in Washington, Nov. 13, 1814. He graduated at Har-

vard college in 1762, and was elected in 1773 representative from Marblehead to the legislature. He at once became a political leader, and an associate of Samuel Adams, Hancock, and Warren. He was placed on the two most important committees, those of safety and supplies, which sat at Cambridge, on the day preceding the battle of Lexington. In January, 1776, he was elected a delegate to the continental congress, signed the Declaration of Independence, was placed on the most important committees, and was generally chairman of the committee of the treasury till the organization of the treasury board in 1780, of which he became presiding officer. He retired from congress in that year, but resumed his seat in 1783. As delegate to the convention which met at Philadelphia in 1787 to revise the articles of confederation, he refused to sign the constitution proposed, but lent it his support as member of congress after it had received the sanction of the people. He served four successive years in congress, and in 1795 retired to private life, residing in Cambridge, till in 1797 he was appointed to accompany Pinckney and Marshall on a special mission to France. He was invited to remain in Paris, though his associates were ordered to quit France, and he then obtained the evidence and assurances upon which the subsequent commission acted. On his return he was unsuccessfully supported by the democratic party of Massachusetts for the office of governor in 1798, and again in 1801, but was elected after an excited canvas in 1810, and was reelected in 1811. In 1812 he was elected vice president of the United States, but died suddenly in the second year of his term.

**GERS**, a S. W. department of France, formed from parts of Gascony and Guienne, bordering on the departments of Lot-et-Garonne, Tarn-et-Garonne, Haute-Garonne, Hautes-Pyrénées, Basses-Pyrénées, and Landes; area, 2,425 sq. m.; pop. in 1872, 284,717. The surface is in general hilly. It is watered by the Gers (which rises in Hautes-Pyrénées, and flows N. into the Garonne), Save, Adour, and several other rivers. The most important vegetable products are the cereals, flax, and onions. Fruit is scarce. Large quantities of wine and brandy are made, but of ordinary quality. The minerals are of little consequence, but gypsum and a fusible spar used in making glass and porcelain abound. The only manufactures are brandy, coarse woollens, leather, bricks, glass, and earthenware. It is divided into the arrondissements of Auch, Mirande, Condom, Lectoure, and Lombez. Capital, Auch.

**GERSON, Jean Charles de**, a French theologian, born at Gerson, near Rheims, Dec. 14, 1363, died in Lyons, July 12, 1429. At the age of 14 he went to Paris to study the humanities and theology, and in 1387 he was selected by the university as one of its deputies to the antipope Clement VII. at Avignon upon the controversy concerning the immaculate conception. About 1393 he was made chancellor

tation, and are often substituted for wines of the Rheingau. The district of Oberingelheim produces much red wine, resembling burgundies of the second and third class, from Burgundy grapes. The produce of the Nahe is nearly related to the middling growths of the Palatinate.—The Bavarian wines, grown in Lower Franconia, in the valley of the Main, are distinguished rather for their body and strength than for their bouquet, and are mostly consumed within the country. The only varieties exported are those produced in the neighborhood of Würzburg, where about 4,500 acres are under cultivation. The best vineyards are the Leiste and the Stein, the products of which are of fine quality and very expensive. Both are situated on the Main, and the former is principally owned by the king of Bavaria, who stores the wine made from the estate in the cellars which underlie the royal castle of Würzburg. In these cellars are more than 280 large casks, some having a capacity of 2,500 gallons. Though considered in the last century indispensable to the proper ripening of wine, they are now but little used. The Leiste wine of good quality is mostly carried to Munich and drunk at court, and only a small quantity enters into trade. The Stein wine, which is also very celebrated, is sold in short-necked bottles of a peculiar shape, called *Bockbeutel*. Much of the wine passing under this name in England and the United States is the product of the Palatinate, which at Mentz and elsewhere is put into bottles of the shape of the *Bockbeutel* and sold as Stein.—In Baden a large quantity of third or fourth class wine is produced, the best growth being the white Markgräfler and the Affenthaler, a light, agreeable red wine. The great tun in the castle of Heidelberg was formerly filled with a wine grown in a district known as the Bergstrasse, which commences at Zwingenberg, in the province of Starkenburg, and follows a range of hills to Heidelberg.—More than half of the wine grown in Würtemberg is produced in the valley of the Neckar, and though not of high grade is agreeable to the taste and wholesome. From its changeable color it is termed Schiller.—The general character of the wines grown in the valley of the Moselle is that of thin Rhine wine. They are lighter and less spirituous than those heretofore described, and are noted for an aromatic flavor, which, however, is said to be generally communicated to the wine by mixing with it a tincture of elder flowers, called also the "essence of muscatel," because it resembles the concentrated flavor of the muscatel grape. Messrs. Thudicum and Dupré, in their "Treatise on the Origin, Nature, and Varieties of Wine" (London, 1872), say: "It must be declared with emphasis that there is not a grape of muscatel grown upon the Moselle fit for wine making; that there is not a single barrel of wine made there which naturally has the muscatel flavor; and that

all the wine having the flavor which imitates it is made up with tincture of elder flowers." The better sorts are highly esteemed in Germany for their supposed medicinal properties. The wines held in highest repute are the Brauneberger and Scharzberger, the latter grown on the Saar, a tributary of the Moselle; and scarcely less noted are the Zeltinger, Graacher, Dun, Piesporter Auslese, Josephshoff, Berncastel, Grünhausen, and Scharzhoffberger. The area under cultivation comprises about 23,000 acres, yielding in favorable seasons 160 gallons to the acre.—About 50 years ago sparkling wines were first manufactured in Germany at Esslingen and Heilbronn, from the Neckar grape; and the process has since been so successfully carried on that these wines may be considered in some degree the rivals of champagne. Upward of 2,000,000 bottles of sparkling Moselle and sparkling hock are annually made at Hochheim, Mentz, Coblentz, and other places, much of which, by means of false labels, is sold as champagne, and readily passes for such. The process of manufacture is precisely similar to that employed in making champagne. (See FRANCE, WINES OF.) The seasons of 1871, 1872, and 1873 were the most disastrous known to German viticulturists.

**GERMERSHEIM**, a fortified town of Rhenish Bavaria, at the confluence of the Queich and the Rhine, 7 m. S. W. of Spire; pop. in 1871, 6,223. It has several churches and schools, and an active trade in grain, hemp, flax, and fruits. Ship building and fisheries are carried on, and gold is washed from the sands of the Rhine. Originally a Roman stronghold, the present town was founded by the emperor Rudolph of Hapsburg, who died here in 1291. It formed part of the electoral Palatinate from 1330 to 1622, when it was conquered by Austria. From 1644 to 1650 it was occupied by the French, who retook and devastated the place in 1674 under Turenne. After the death of the elector Charles (1685), the French again claimed possession, whence arose the Germersheim war of succession, which came partly to an end through the treaty of Ryswick (1697), and finally through the arbitration of the pope (1702). It was subsequently the scene of important military operations up to July, 1793, when the French were here defeated by the Austrians. Germersheim having been made a fortress of the German confederation, works have been in progress since 1835, forming together with the fortress of Landau, distant 10 m., and with a tête-de-pont on the right bank of the Rhine, a strong strategical position.

**GEROK, Karl**, a German prelate and poet, born at Vaihingen, Würtemberg, Jan. 30, 1815. He studied at the gymnasium of Stuttgart, held various ecclesiastical offices, and in 1868 was appointed first preacher of the court and chief consistorial councillor. His published sermons have passed through many editions, and his religious poems, including

*Pfingstrosen* (4th ed., 1870) and *Palmblätter* (17th ed., 1871), have made him famous. Besides his poems *Blumen und Sternen* (3d ed., 1870), he published during the Franco-German war of 1870-'71 patriotic effusions under the title of *Deutsche Ostern*.

**GÉRÔME, Jean Léon**, a French painter, born in Vesoul, May 11, 1824. In 1841 he went to Paris and studied under Paul Delaroche, whom he accompanied to Italy. He returned to Paris in 1845, and exhibited his first picture in 1847. For several years afterward he travelled in the East, his journeys furnishing him with numerous subjects for pictures. He obtained medals in 1847, 1848, and 1855, and in the last year received the decoration of the legion of honor. In 1863 he became professor of painting in the school of fine arts, and in 1869 was decorated with the order of the red eagle. He has produced many pictures of the life of the ancients, which have placed him at the head of a school of art designated as the Pompeian or New Greek; and several of his pictures have been criticised as indelicate to the last degree. Among his works are "The Virgin, the Infant Jesus, and St. John," "Bacchus and Cupid," "A Greek Interior," the frieze of the vase commemorative of the London exhibition of 1851, "The Plague at Marseilles," "The Death of St. Jerome," and "A Lioness meeting a Jaguar." His masterpiece in historical art is "The Age of Augustus and the Birth of Jesus Christ," exhibited in 1855, and purchased by the French government. He exhibited in London in 1871 a naked Nubian girl, entitled "To be Sold," and "Cleopatra brought to Cæsar in a Basket," the latter inferior to most of his other works. One of his latest pictures, "The Gladiators," was purchased in 1873, by Mr. A. T. Stewart of New York, for 80,000 francs.

**GERONA.** I. A province of Spain, in Catalonia, forming the N. E. extremity of the peninsula, bordering on France and the Mediterranean, and on the provinces of Barcelona and Lérida; area, 2,272 sq. m.; pop. in 1870 (estimated), 325,110. The surface is chiefly covered with the ramifications of the Pyrenees, but fertile valleys frequently intervene. The inhabitants of the interior are mostly engaged in agriculture and cattle rearing; those of the coast in ship building, fishing, and navigation. The principal rivers are the Ter and the Fluvià. Among the towns are Rosas and Figueras, both fortified, Olot, and Ripoll. II. A city (anc. *Gerunda*), capital of the province, at the confluence of the Ter and Oña, 52 m. N. E. of Barcelona; pop. about 10,000. The chief manufactures are linen and woollen fabrics, paper, soap, earthenware, and hardware. It was captured by Charlemagne, regained by the Moors, and is famous for the sieges it has sustained.

**GERRY, Elbridge**, an American statesman, fifth vice president of the United States, born in Marblehead, Mass., July 17, 1744, died in Washington, Nov. 13, 1814. He graduated at Har-

vard college in 1762, and was elected in 1772 representative from Marblehead to the legislature. He at once became a political leader, and an associate of Samuel Adams, Hancock, and Warren. He was placed on the two most important committees, those of safety and supplies, which sat at Cambridge, on the day preceding the battle of Lexington. In January, 1776, he was elected a delegate to the continental congress, signed the Declaration of Independence, was placed on the most important committees, and was generally chairman of the committee of the treasury till the organization of the treasury board in 1780, of which he became presiding officer. He retired from congress in that year, but resumed his seat in 1783. As delegate to the convention which met in Philadelphia in 1787 to revise the articles of confederation, he refused to sign the constitution proposed, but lent it his support as member of congress after it had received the sanction of the people. He served four successive years in congress, and in 1795 retired to private life, residing in Cambridge, till in 1797 he was appointed to accompany Pinckney and Marshall on a special mission to France. He was invited to remain in Paris, though his associates were ordered to quit France, and he then obtained the evidence and assurances upon which the subsequent commission acted. On his return he was unsuccessfully supported by the democratic party of Massachusetts for the office of governor in 1798, and again in 1801, but was elected after an excited canvas in 1810, and was reelected in 1811. In 1812 he was elected vice president of the United States, but died suddenly in the second year of his term.

**GERSE**, a S. W. department of France, formed from parts of Gascony and Guienne, bordering on the departments of Lot-et-Garonne, Tarn-et-Garonne, Haute-Garonne, Hautes-Pyrénées, Basses-Pyrénées, and Landes; area, 2,495 sq. m.; pop. in 1872, 284,717. The surface is in general hilly. It is watered by the Gers (which rises in Hautes-Pyrénées, and flows N. into the Garonne), Save, Adour, and several other rivers. The most important vegetable products are the cereals, flax, and onions. Fruit is scarce. Large quantities of wine and brandy are made, but of ordinary quality. The minerals are of little consequence, but gypsum and a fusible spar used in making glass and porcelain abound. The only manufactures are brandy, coarse woollens, leather, bricks, glass, and earthenware. It is divided into the arrondissements of Auch, Mirande, Condom, Lectoure, and Lombez. Capital, Auch.

**GERSON, Jean Charles de**, a French theologian, born at Gerson, near Rheims, Dec. 14, 1363, died in Lyons, July 12, 1429. At the age of 14 he went to Paris to study the humanities and theology, and in 1387 he was selected by the university as one of its deputies to the antipope Clement VII. at Avignon upon the controversy concerning the immaculate conception. About 1398 he was made chancellor

of the university of Paris. Charles VI. had just fallen into insanity, and while divisions menaced the state, the church was rent by a schism which produced two and afterward three pretenders to the pontificate. Gerson exerted himself for the reform of morals and the banishment of scholasticism from the university, combated astrology, and resisted the invasion of the pantheistic doctrines which then had their seat in Brabant. When the duke of Orleans was assassinated by the duke of Burgundy in 1407, Gerson denounced the murderer and delivered the funeral oration of his victim. Pursued by John the Fearless, he saw his house pillaged, and was obliged to conceal himself in the vaults of Notre Dame. He was present in the council of Constance as theologian of the bishop of Paris; and, as the council had been convened for the purpose of electing a pope whom all Christendom would acknowledge, he urged the deposition of the two pretenders to the papacy, John XXIII. and Benedict XIII., in a treatise *De Auferibilitate Papæ*. He wished to prove that there are circumstances in which the assembled bishops of the whole church can compel pretenders to the papal dignity to renounce their claim, and depose them if they refuse to abdicate. The schism was at length ended, but Gerson's efforts to check the abuses which reigned in the church were ineffectual; and as civil dissensions did not permit his return to France, he retired to the mountains of Bavaria, where he wrote *De Consolatione Theologiae*, and the *Monotessaron*, a harmony of the four Gospels. He returned to his country after a voluntary exile of two years, and found an asylum in a convent. Though one of the most active men of his age, he was also the most mystical of its thinkers. He was the first who sought to give to mysticism the character of a science. He recognized in the soul two classes of faculties: the cognitive or intellectual, whose highest act is simple intuition of divine things; and the affective faculties, whose highest act is ecstatic delight in God. To substitute this mystical philosophy for scholasticism was the aim of his writings. As many manuscripts of the "Imitation of Jesus Christ" bear the name of Gerson, that work is often ascribed to Gerson. (See KEMPIS, THOMAS A.) See *Vie de Gerson* (Paris, 1832); C. Schmidt; *Essai sur Jean Gerson* (Strasbourg, 1839); and R. Thomassy, *Jean Gerson* (Paris, 1843). The best edition of Gerson's works is that of Dupin (5 vols. fol., Antwerp, 1706).

**GERSON BEN JUDAH**, a rabbi of France, distinguished by the appellations *Rabbenu* (our master), *Hazziken* (the old man), and *Meor haggolah* (light of the exiled), born in Germany about 960, died about 1030. He wrote a commentary on the Talmud, of which only slight fragments remain, and is celebrated for the introduction of various reforms among the European Jews, including the abolition of polygamy and repudiation, known under the name of "institutions (*gezeroth*) of Rabbenu Gerson."

**GERSTÄCKER, Friedrich**, a German traveller and novelist, born in Hamburg in May, 1816, died in Vienna, May 31, 1872. After a brief term in a commercial school he was apprenticed to a grocer in Cassel; but becoming dissatisfied, he ran away on foot to Bremen, and in the spring of 1837 engaged as cabin boy on board a vessel bound for New York. He led a wandering and adventurous life in the United States for several years, a part of which was spent as a hunter and trapper among the savages of the Indian territory. In 1842 he bought a hotel at Point Coupée, Louisiana; but this having proved a bad speculation, he returned in 1843 to Germany and engaged in literary pursuits, publishing *Streif und Jagdzüge durch die Vereinigten Staaten Nordamerikas* (1844); *Die Regulatoren in Arkansas* (1846); *Mississippibilder* (1847); *Die Flusspiraten des Mississippi* (1848); *Amerikanische Wald- und Strombilder* (1849); and several minor works and translations. In March, 1849, he set out on a journey around the world, during which he visited South America, California, the Hawaiian islands, Australia, and Java, and returned to Germany in 1852, making his residence at Leipsic. An account of this trip was published under the title of *Reisen* (5 vols., 1853-'4). During the succeeding four years he published a number of novels. In 1860 he made an extensive tour through South America, visiting Ecuador, Peru, Chili, Uruguay, and Brazil, and returned home the following year. In 1862 he accompanied Duke Ernest of Gotha to Upper Egypt, Nubia, and Abyssinia, and in 1863 he visited the Central American states. He set out in 1867 on another journey around the world, visiting first the United States, Mexico, and South America. He went thence to the Pacific isles, and after an extended tour returned to Europe, and published a number of novels illustrative of the countries through which he had passed. Some of his later works are: *Neue Reisen durch die Vereinigten Staaten, Mexico, Ecuador, Westindien und Venezuela* (1868); *Die Missionäre* (1868); *Die Blauen und die Gelben* (1870); *Bunter Treiben* (1870); *In Mexico* (1871); *Hamburger Nachrichten* (1871); *Herrn Mahlhuber's Reiseabenteuer* (1871). Several of his works have been translated into English.

**GERVINUS, Georg Gottfried**, a German historian and statesman, born in Darmstadt, May 20, 1805, died in Heidelberg, March 18, 1871. He was educated at the university of Heidelberg, afterward spent several years in Italy, and on his return to Heidelberg in 1835 was appointed extraordinary professor. He had already published *Geschichte der Angelsachsen im Ueberblick* (1830), and *Historische Schriften* (1833), and in 1836 he was appointed professor of history and literature at Göttingen. He had now begun *Die Geschichte der poetischen Nationalliteratur der Deutschen* (1835-'8), which was supplemented by the *Neuere Geschichte*, &c. (1840-'42). In the latest edition (5 vols.,

torian of Switzerland, one of the classical historiographers of Germany (1752-1809); Georg Forster, the teacher and friend of Alexander von Humboldt, an admirable writer; the publicist Friedrich Karl von Moser; the educator Basedow, and afterward Pestalozzi; Campe, the writer of books for children; Nicolai, the friend of Lessing and author of the satirical novel *Salduus Nothanker*; Adelung, the philologist; Böttiger, the antiquary; Sturz, the biographer; Reimarus, Jerusalem, Spalding, Michaelis, Rosenmüller, and Ernesti, in theology; Eichhorn in theology and universal and literary history; Blumenbach, Bloch, Herschel, Euler, Vega, and many other eminent writers in various branches of learning and science, belong to this period.—A peculiar and powerful writer, who stood quite alone in his idiosyncrasies, was Jean Paul Friedrich Richter (1763-1825). He puzzles the reader by his inability to assort his thoughts, which he pours out with the reckless *naïveté* of a childlike soul; but the obscurity is lighted up by flashes of humor and brilliant gems of thought and feeling. The influence of this genial philosopher was great, especially upon the women of Germany. Novalis (Von Hardenberg, 1772-1801) was another strangely constituted writer, who uttered himself in poetic sighs rather than in vigorous words; but amid his morbid sentiments are scattered thoughts of such wisdom and spiritual insight that his poems and prose writings, although few and fragmentary, gave him a place among the classical authors of his country. He is regarded as the head of the so-called romantic school, which draws its inspiration from the fabulous, mediæval and chivalric eras of literature and history. Among the most brilliant masters of this school was August Wilhelm von Schlegel (1767-1845), the author of an antique tragedy, *Ion*, and of romances and elegies, but chiefly distinguished for his admirable metrical translation of Shakespeare, his critical and æsthetic writings, his lectures on the drama and its literature, and his labors connected with Indian literature and the Sanskrit language. His brother Friedrich von Schlegel (1772-1829) was also engaged in the study of Hindoo literature; but his specialty was the history of ancient and modern literature and the philosophy of history. The most original representative of this school was Ludwig Tieck (1773-1853), whose poetical dramatization and collection of ancient fairy and popular tales reflect the romance of mediæval poesy with beauty and genius, but with a mystic feeling bordering almost on superstition. The writings of Tieck's friend Wackenroder (1772-'98) were the first to enlist the sympathies of the German artists for the æsthetic principles of the romantic school. La Motte Fouqué (1777-1843), of the same school, stands alone in German literature by his remarkable delineations of fairy lore, as for instance in his tale of *Undine*. Chamisso (1781-1838), the author of *Peter Schlemihl* and of many fine lyrics, Tiedge (1752-1841), the author of the philosophic poem *Urania*, the Aristophanic *Platen* (1783-1835), and the mystic religious poems of Verner, all belong to this romantic school; with but few exceptions, as for instance patriotic and spirited poet Seume (1763-1835), most writings of this period are tinged with morbid passion for romantic and æsthetic views of life. This epoch comprises the poets Schenkendorf (1783-1817), Stäudlin (1763-1840), Kosegarten (1758-1818), Bösen the Dane (1764-1826), Matthiessen (1781-1831), Mahlmann (1771-1826), Salis (1781-1834), and Eichendorff (1788-1857), seven of whom belong to the romantic school. As novelists and tale writers are Achim von Arnim (1784-1831) and Clemens Brentano (1778-1842), the compilers of a series of celebrated popular songs (*Des Knaben Wunderhorn*). Ernst Theodor Amadeus Hoffmann (1776-1822), the author of many wild, fantastic and legends (*Elizir des Teufels, Kater &c.*), which cap the climax of the super-naturalistic element of the romantic school. The favorite novelists of this period are Hermes (1738-1821); Hippel (1741-'96), indiscreet friend and disciple of Kant; Müllner (1735-'87), the author of a collection of *Fairy Tales* or popular fairy tales; Laube (1759-1831), a type of the most sentimental novelists; Blumauer, J. G. Müller, and Schlegel (1738-1817), the author of a novelization of Sterne's "Sentimental Journey." Jung-Stilling (1740-1817), the inspired tale writer whose naïve and original autobiography G. Schiller, and Herder took so much notice of. Knigge (1752-'96), the author of the *Braunschweig*; and Immermann (1796-1860), the author of the famous story of *Münchhausen*. Ghost stories were for a time made popular by Schiller's *Geisterseher*, and to this day the tales of literature Jung-Stilling also contributed to. Associated with the romantic school from the earlier part of her literary career, was Rahel Levin von Arnim (1785-1859), celebrated by her correspondence with Goethe. Rahel Levin Varnhagen von Ense (1771-1833), a Jewish woman of much greater talent and originality of thought. Among other authoresses are Auguste von Pausanias, Hahn-Hahn, Amalie Schoppe, Johanna Penhauer, Friderike Brun, and Talvj (Mrs. Robinson) contributed to the knowledge of Servian popular literature and Slavic literature generally, and were distinguished in this and other spheres of literature.—The efforts of Klopstock, Herder, and other authors to revive the popular early German poetry, as well as the efforts of nationality which was rooted in the mind of this century by the influence of Napoleon I., contrived to give a powerful impulse to the renaissance of ancient German literature, to a great extent fostered by Jahn's *Deutsches Volksthum*. Von

edition of the *Nibelungen*, did much to promote a love for the study of the old German dialects and the poetry connected with them. The brothers Wilhelm and Jakob Grimm are the more immediate founders of this new branch of philological and poetical investigation. Benecke, Lachmann, and Sinrock labored in the same direction, and more recently Moritz Haupt; also Franz Pfeiffer, Oskar Schade, Zarneke, Holtzmann, Hoffmann von Fallersleben, Bartsch, &c.—The German war of independence against Napoleon I. produced some striking patriotic songs from Prof. Arndt of Bonn (1769–1860), and Theodor Körner (1791–1813), the gallant soldier-poet, and author of *Leier und Schwert* ("Lyre and Sword"). Some of the lyrical poets of the romantic school whom we have named also became distinguished for their patriotic effusions, especially Schenkendorf and Stägemann. Wilhelm Müller of Dessau (1794–1827), author of the admirable *Griechenlieder*, may be classed among patriotic poets. The maiden efforts of Friedrich Rückert (1789–1866), one of the best lyrical and didactic poets of Germany, and celebrated as much for his imitations of troubadour songs as for his versions of oriental poetry, were also inspired by the war against the French. Another who came forward as a champion of national independence was Uhland (1787–1862), the chieftain of the modern Swabian school, and one of the leading poets of Germany. Stuttgart, the seat of the great publishing house of Cotta and of the critic Wolfgang Menzel, was the headquarters of this school. Hebel (1760–1826), whose *Alemannische Gedichte* were greatly admired by Goethe, belonged to it by the Swabian dialect and spirit of his songs, although he lived at an earlier period. An eminent lyrical poet of this school was Justinus Kerner. Gustav Schwab, Pfizer, the critic and historian, Karl Mayer, and Mörike, all belong more or less to the Swabian school. A new direction was given to literary activity by the political excitement immediately preceding and succeeding the French revolution of 1830. Ludwig Börne (1786–1837) and Heinrich Heine (1800–1856) are regarded as its heralds, the former by his pungent and comprehensive political satires, the latter by his keen insight and peculiar lyrical genius. Heine exercised a wide influence in the literary world. As a poet, he had a peculiar gift of uniting the tragic and comic in a felicitous and racy manner, which made him the idol of a new school of authors who styled themselves "Young Germany," but who partook much less of Heine's poetical gifts than of his political sympathies. Karl Gutzkow (born in 1811) was the head of this school. He is the author of *Die Ritter vom Geiste* and *Zauberer von Rom*, and of many other novels, and several dramas. The other principal representatives of "Young Germany" are Heinrich Laube (born in 1806), Gustav Kühne (1806), and Theodor Mundt (1808). An emi-

nent author of this period is Baron Sternberg (1806), author of *Diane* and *Paul*, and of many other works which hold up the mirror to the social and political condition of his country. Another famous writer and amateur liberal politician of this class is Prince Pückler-Muskau (1785–1871), author of *Briefe eines Verstorbenen*, and of other piquant books. The taste for novels of a political and social tendency has been characteristic of German writers since the early part of this century. The novels of Gutzkow, Laube, and many other contemporary German writers, all belong to this category, while Gustav Freytag has gained a high reputation by several excellent novels, among which the best known is *Soll und Haben* ("Debit and Credit"). The line of historical novelists was opened by Meissner (1753–1807); he was followed by Karoline von Pichler (1769–1843), Tromlitz (Von Witzleben, 1773–1839), Van der Velde (1779–1824), Karl Spindler (1796–1855), author of *Der Jude*, *Der Bastard*, and other novels, which enjoyed great popularity; Rellstab, Storch, Rau, and Koenig (1790–1869), author of *Die Clubisten in Mainz* (1847). Berneck or Bernd von Guseck (born in 1803), Mügge (1806–'61), author of *Toussaint* and other excellent novels, Kühne and Heller (1813–'71), are all contributors to this class of novels. Here belong also the semi-historical novels of Louise Mühlbach (Mme. Mundt, 1814–'73), which have enjoyed a very wide popularity, but are not entitled to high rank either from a literary point of view or as interpreters of history. A far higher merit must be awarded to Zschokke (1771–1848), one of the best German prose writers of recent times, author of many excellent historical and romantic works, and of *Stunden der Andacht*, a religious work, which has passed through many editions. Heinrich Steffens, the Norwegian philosopher and naturalist (1773–1845), wrote German novels based upon Scandinavian history, which are replete with interest. Another historical novelist is Wilhelm Häring, known by the pseudonyme of Wilibald Alexis (1797–1871), who imitated so skilfully the manner and style of Sir Walter Scott that several of his works were translated into foreign languages and passed for some time as the productions of the great English romancer. The most famous of the kind is "Walladmor." Hauff, a genial novelist, whose *Lichtenstein* takes high rank among historical romances; Clauren, a licentious writer, but one whose novels have been read extensively; and Hackländer, the author of *Soldatenleben*, *Handel und Wandel*, and many other works, and the founder and conductor of the widely known journal *Ueber Land und Meer*, may be mentioned here; also Berthold Auerbach (1812), who attracted immediate attention by his first work, *Schwarzwälder Dörfgeschichten*, and has since taken his place among the leaders of German fiction, his novel *Auf der Höhe* having gained a very wide reputation in Germany,

the Far West of the United States" (English edition, 1859). Hettner (born 1821) has written sketches of his travels in Greece. Friedrich Gerstäcker (1816-'72) is the author of many entertaining and humorous descriptions of travels, especially in the new world. Another pleasing narrator of his journeys is Mundt. A voluminous writer of travels is the tourist Kohl (born 1808). Ida Pfeiffer (1797-1858) showed herself a most intrepid and indefatigable tourist and valuable contributor to the literature of travel. Germany has also given birth to some of the most celebrated recent explorers of remote parts of the world, as Gützlaff in China, Siebold in Japan, Barth, Vogel, Nachtigall, Gerhard Rohlfs, and Heuglin in Africa, the brothers Schlagintweit in central Asia, Bastian in S. E. Asia, and Leichhardt in Australia.—We complete this sketch by a list of eminent men (mostly living) in the principal departments of learning, including some names already mentioned. In the natural sciences: Burmeister, Ule, Johann Müller, Carus, Rossmässler, Dove, Giebel, Masius, Valentin, Moleschott, Büchner, Vogt, Oken, Virchow, Burdach, Schleiden, Bernhard Cotta, Nees von Esenbeck, Leopold von Buch, Endlicher, Martius, Naumann, Bischoff, Liebig, Bunsen, Kirchhoff, Kopp, Poggenдорff, Rose, Erdmann, Gmelin, Wöhler, Wackenroder, Gehler, Vogel, Mitscherlich, Pringsheim, Schödlér, Du Bois-Reymond, Fechner, O. Schmidt, F. Cohn, Reichenbach, Unger, Weber, Mohl, Steinheil, Rau, Pietschmann, Reich, Hagen, Lang, Karl, Schrauf, Wundt, H. Grassmann, Hallier, Kummer, Mann, Hartung, Gegenbaur, Fürbinger, Hoffmann, S. Hartmann, Haeckel, Völker, RameLOW, Kupffer, Winkler, Kunth, Fitzinger, Emmerling, Fresenius, Wagner, Meissner, Vom Rath, Baumgärtner, Erdmann, Hofmann, Karmarsch, Würtz, Zwick, Otto, Reis, Robert Grassmann, Zirkel, G. Hartwig, Credner, Pfaff. In medicine: Johann Müller, K. Thiersch, Burdach, Wagner, Ehrenberg, Hecker, Carus, Blasius, Froriep, Schönlein, Skoda, Dieffenbach, Mitscherlich, Romberg, Weber, Donders, A. von Gräfe, Virchow, Steinthal, Reich, W. Roth, Busch, Haussmann, Armbrecht, Klebs, Nothnagel, Schröder, Steinbacher, Kunze, Fürst, Stilling. In astronomy and mathematics: Bessel, Encke, Struve, Mädler, Galle, Gauss, Lejeune-Dirichlet, Argelander, Heis, Schmidt, Dienger, Förster, Schucht, Göbel, Osterdinger, Zöllner, Greiffenstein, K. S. Neumann, Möbius, Weisbach, H. J. Klein, Volger, Bischof. In military science, engineering, &c.: Möwes, Taubert, Rebhann, Hagen, Dittmer, Schmitt, Winkler, Lieber, Zastrow. In geography, ethnology, statistics, and travels: Carl Ritter, Daniel Wappäus, Ungewitter, Berghaus, Petermann, Möller, Stein, Streit, Handtke, Löher, Raumer, Haxthausen, Dieterici, Hübner, Sydow, Möllhausen, Mauch, Munzinger, Hügel, Roon, Schweinfurth, Semper, Seemann, Ziegler, Waitz, Schmarda, Blan, Berlepsch, Pauli, Stieler, Fritsch, Stephan, Stangl, Rodenberg, Steinthal, Cornelius, Langhans, Hartmann. In history and biography: Wachler, Gfrörer, Pölitz, Leo, K. A. Menzel, Preuss, Weber, Prutz, Varnhagen von Ense, Pertz, K. W. Böttiger, Zimmermann, Von Rochau, G. Curtius, Dittmer, Spiegel, S. Bauer, Fessler, Wolff, Just, Zuntz, Grätz, Stockmar, Honegger, Grotefend, Stahl, Elze, Ungewitter, Hagenbach, K. Mendelssohn-Bartholdy, Caspari, Kolb, Holtzendorff, Ukert, Rosenkranz, Brandes, Gentz, Nitzsch, Hirsch, Stoffel, F. Arndt, W. Müller, Wackernagel, Sybel, Kohlrausch, Caro. In the history and criticism of literature, philosophy, art, and aesthetics: Gervinus, Vilmar, Wackernagel, Julian Schmidt, Solger, Bouterwek, Vischer, Schwegler, Ruge, Wolf, Koberstein, Gottschall, Stern, Schell, Kreyssig, Kurz, Lindau, Carrière, Eye, Stahr, Hauptmann, Elze, Meissner, Klein, Gervais, Ethé, Wagner, Zimmermann, Hirzel, J. W. O. Richter, Löper, Schasler, Weiss, Lenz, Liszt, J. P. Richter, Lübke, Fechner, J. H. Schmidt, H. Grimm, Eggers, Lütke, Vogler. In philology: F. A. Wolf, Schaaf, Maerker, Heinsius, Heyse, K. F. Becker, Massmann, Wilhelm von Humboldt, Zumpt, Hermann, Niebuhr, Bernhardt, Creuzer, Wachler, Con. Schneider, Ernesti, E. and G. Curtius, Matthiae, Thiersch, Jacobs, Buttmann, Rost, Passow, Kühner, Ramshorn, Döderlein, Freund, Gerhard, Gesenius, Nork, Bopp, Freytag, Jahn, Hitzig, Hupfeld, Ewald, A. F. Hoffmann, Lassen, Sachs, L. Geiger, Steinschneider, Levy, Tischendorf, Wattenbach, Lepsius, Schrader, Teuffel, Westermann, Meineke, Leo Meyer, Kremer, Obermüller, Dietz, Brambach, E. H. Arndt, Wollheim da Fonseca, Delitzsch, Holtmann, Rödiger, Stark, Westphal, Böttlingk, Fick, Schleicher, Schott, Cuno, Zenker, Dindorf, J. Müller, Roth, Benfey, Hildebrand, Grassmann, Quenstedt. In political science and jurisprudence: Savigny, Stahl, K. F. Eichhorn, Gans, Hüllmann, Welcker, Schubert, Stein, Bülow, Mohl, Gentz, Von Rönne, R. W. Dove, Holtzendorff, Gneist, the Swiss Bunsen, Barth, Glaser, Gerber, Marx, Richter, Marr, Adler, Oppenhoff, Maurer, Mittermaier, Mohl, Perthes, Schwarze, Twisten, Joseph Cager, Richthofen. In theology, philosophy, and Biblical sciences: Fessler, Martin, Luthardt, Rothe, Hefele, Ketteler, Döllinger, Alzog, Dörner, Guericke, Schenkel, Ullmann, Strass, Schleiermacher, Roh, Pottgeisser, Keil, Delitzsch, B. Baur, F. C. Baur, Reiske, Reinken, Leonhardi, Schulte, Ulrich, Braubach, A. von Hartmann, Frohschammer, J. B. Meyer, Zeising, Nietzsche, Ueberweg, Stier, Aub. Krummacher, Balzer, Lange, Tholuck, Tischendorf, Friedberg, Menzel, Kirchmann, Fischer, A. Geiger, Frankel, Hirsch, Philippon, Klein, Luz, Baumann, Winer, Tuch, Kurtz, Schrader, Ludwig Feuerbach, Schopenhauer, E. von Hartmann. In the science of education: Diesterweg, Froebel, Gräfe, K. Schmidt, Fricke, Schlosser, Dillmann, Beck, Hill, Lahker, Schmelzer, L. W. Seyffarth, Böhm, Schott, Westermann, Möbius, Rosenkranz, Waitz.

with political and commercial relations; Raumer (1781-1873), the historian of the Hohenstaufen; Leopold von Ranke (1795), whose labors embrace a vast field of modern history; Dahlmann (1785-1860), the German Guizot, author of "Sources of German History," and the historian of Denmark and of the English and French revolutions; and Gervinus (1805-'71), the historian of German literature, Shakespearean critic, and author of the great history of the 19th century. Here may be mentioned also Rotteck (1775-1840), whose excellent universal history has been very popular on account of its liberal political views, and Weber, the author of several universal histories. While Niebuhr introduced a profounder method in the study of early Roman history, Bunsen, Lepsius, and others made discoveries in Egyptian and oriental antiquities, and a third impulse proceeded from the active researches in the field of classical archaeology and philology. These combined influences are more or less manifest in the labors in ancient history of Böckh, Karl Otfried Müller, Duncker, Droysen, Mommsen, Kortüm, Adolph Schmidt, Plass, Wachsmuth, Tittmann, Flathe, Manso, Abeken, Schwegler, E. Curtius, Lassen, Jahn, Hermann, Tenfelde, and Movers. In the special study of Sanskrit Roth, Böhtlingk, Benfey, Fick, A. Weber, and others have won distinction. The history of the middle ages has been treated by Röhss, Rehm, and Wilken, and more especially by Leo, Hammer, Fallmerayer, Aschbach, Lappenberg, Dahlmann, Schäfer, Röpell, Kriegk, and Gregorovius. Various branches of oriental history and literature have been actively explored by Joseph von Hammer-Purgstall, Flügel, Plath, Radeloff, Ewald, and Nöldeke. Among writers on modern history are Dohm, Saalfeld, Balan, Münnich, Häusser, and Treitschke. The humanitarian and cosmopolitan direction given to historical studies by the writers and philosophers of the 18th and 19th centuries, and especially by Herder and Kant, is manifest in the comprehensiveness of views which Rotteck, and chiefly Schlosser, bring to bear upon their labors, as well as in many works on particular sections and occupations of the people. This has culminated in what may be designated as a new science, which the Germans call *Culturgeschichte*, i. e., a history which treats of the moral, intellectual, social, and politico-economical, as well as political development of the people. Among the principal laborers in this new sphere of investigation are Wachsmuth (1784-1866), author of *Europäische Sittengeschichte* and of *Allgemeine Culturgeschichte*; Scherr, author of *Geschichte deutscher Cultur und Sitte*; Klemm (1802-'69), author of *Allgemeine Culturgeschichte der Menschheit*, and of *Allgemeine Culturwissenschaft*; and Henne-am-Rhyn, author of *Culturgeschichte der neueren Zeit*. The same tendency to dwell upon the practical realities of life extends over many other departments of literature in Germany, and is most strongly expressed in recent

biographies and autobiographies, especially in that of Perthes. A more physiological method in these branches of investigation has been adopted by Riehl in his *Naturgeschichte des Volks als Grundlage einer deutschen Socialpolitik*. The literature of travels was greatly stimulated by Johann Georg Adam Forster, commonly called Georg Forster (1754-'94), who accompanied Cook on his second voyage round the world, and who, in Alexander von Humboldt's opinion, inaugurated a new era of scientific voyages. A still more powerful impulse was given by Humboldt himself, by his travels in the equinoctial regions of America, and in central Asia. The travels of Lichtenstein (1780-1857) in southern Africa were of great scientific importance. The travels of Prince Maximilian of Wied (1782-1867) furnished valuable additions to the knowledge of the natural history and ethnology of Brazil and the United States. The explorations of Martius (1794-1868) in Brazil are important for the studies of botany, ethnology, geography, and statistics. Pöppig (1797-1868) visited Chili, Peru, and the river Amazon. Among the other explorers of South America are Burmeister (born 1807), who travelled more particularly in Brazil, and Johann Jakob von Tschudi (1818), a relative of Friedrich von Tschudi, author of *Das Thierleben in der Alpenwelt*, and an active traveller, especially in Peru. Sir Robert Hermann Schomburgk (1804-'65), a German by birth, but employed in the service of the British government, travelled in British Guiana, Barbadoes, Hayti, &c. His works were published in German by his brother, Otto Schomburgk (1810-'57). Another brother, Moritz Richard Schomburgk, travelled in British Guiana at the expense of the king of Prussia, and afterward in Australia in company with a fourth brother, Julius Schomburgk. The East has been visited by G. H. von Schubert (1780-1860), especially Egypt, Palestine, and Greece, and by Seetzen (1767-1811), whose *Reisen durch Syrien, Palästina, die Trans-Jordan-Länder, Arabia Petraea und Unterägypten*, were edited by F. Kruse. Minutoli (1772-1846) wrote on his travels to Upper Egypt. Rüppell (born 1794) explored Nubia, Kordofan, Arabia Petraea, and is best known by his travels in Abyssinia. The most eminent writers on Egypt are Lepsius, Brugsch, Baron Bunsen, Ebers, Dümichen, and Lauth. The historian Raumer gave graphic descriptions of his travels in Venice, England, Italy, and the United States; and Joseph Russegger (1802-'63) wrote comprehensively on his travels in Europe, Asia, and Africa. Venedey (1805-'71) gave accounts of England, Ireland, and southern France. Moritz Wagner (born 1813) has published his travels in Algeria, the Caucasus, Colchis, Persia, and Kurdistan, and, in conjunction with his companion Scherzer, in North America and Costa Rica. Fröbel (born 1806) has described "Seven Years' Travels in Central America, Northern Mexico, and

wine of each year. The quantity of wine annually produced has varied from 25 pieces of 240 gallons each to 60 pieces. The wines of inferior quality, produced in poor years, are sold by auction immediately after the spring racking, and only the select qualities are kept in the cellars of the estate. At the age of four or five years they are bottled, after which they greatly improve in bouquet. The largest yield was in 1857, when 60 pieces, or 14,400 gallons, realized at auction \$60,000. The difficulty of obtaining genuine Schloss-Johannisberger is very great, and large quantities of spurious wine are sold under the name. The first quality has been known to command from \$5 to \$8 a bottle; but the auction wines are much less valuable, and sell for from \$250 to \$1,000 the piece, according to the qualities they possess for mixing.—Next in reputation to the Johannisberger wine, if not its equal, is that produced on the estate of Steinberg, which until 1866 was the property of the dukes of Nassau, but in that year passed into the possession of the crown of Prussia. The Steinberg is a hill 3 m. from the Rhine, the vine-growing portion of which occupies an area not exceeding 60 acres, enclosed by a massive wall of masonry. This, with the mountain barrier in the rear, effectually screens the vineyard from chilling or injurious winds. The estate, which once belonged to the wealthy cloister of Eberbach, includes also a farm of 450 acres, maintained for the sole purpose of producing the manure necessary for the vineyard. The latter has various undulations and hollows, by which it is divided into districts yielding different qualities of wine. The soil is heavier than that of the Schloss Johannisberg, and on this account in warm seasons the ripening of the grape is not as a rule effected before the latter has reached its full maturity. The opposite result is often witnessed in the Johannisberg vineyard. Thus, during the years 1857, 1858, and 1859, which were exceptionally warm, the Steinberg wines showed a marked superiority over those of the Johannisberg. The discovery that the over-ripe grapes yield the best wine was made on this estate about 50 years ago, and since then the vintage has always been very late. In ordinary years there are two or three selections of grapes, from the first of which is made the best wine, the rest hanging 10 or 15 days longer. The annual product of the estate varies from 14,000 to 20,000 gallons, valued at \$350 to \$3,500 the piece, the latter price being paid for the choicest cabinet wines only. The *Auslese* of certain exceptionally fine years has sometimes sold in the cask as high as \$5 a bottle. The ordinary qualities, like those of the Johannisberg wine, are sold annually by auction.—Scarcely inferior to these wines are those produced on the Rüdesheim-Berg and Hinterhaus, which have a southerly exposure, and lie so near the Rhine that the reflection of the sun from the surface of the river greatly facilitates the ripening of the grape. The vine-

yards, comprising an area of about 300 acres, divided among a number of proprietors, are terraced from the base to the summit of the hills, and yield wines of considerable body and fine bouquet, the best qualities of which are high-priced. A short distance below Rüdesheim is Asmannshausen, which yields the very good red wine of the Rheingau. This is produced from the black Burgundy grape known as the *pinen noir*, whence the wine is often spoken of as a species of Rheinish burgundy. It has a soft and exceedingly delicate flavor, but like the higher class of burgundies suffers from transportation. The wines produced on the estates of Marcobrunn, Hattenheim (first growth), Gräfenberg (first growth), and Geisenheim-Rothenberg, also rank as of the highest quality, and in favorable seasons command enormous prices. Of the second growth of the Rheingau produce, the most esteemed varieties are the Johannisberg-Claus, Vollrath, and Rantental-Berg. Among the third growths may be mentioned Hattenheimer, Winkel, Hallgarten, Rüdesheimer, Geisenheimer, Erbach, Eltville, and Lorch, which may be regarded as the ordinary wines of commerce. In good seasons and when the best grapes only are selected, these latter growths sometimes reach a high degree of excellence, and command a correspondingly high price.—The banks of the Rhine from Asmannshausen to Coblenz are planted with vineyards, but the situation is for the most part unfavorable, and the wine of first-rate quality is produced only in part of the river. But in the valley of the little river Ahr, which enters the Rhine about 20 m. below Coblenz, is grown a most excellent wine, called the Ahr-Bleichart, having a strengthening and astringent quality, and an agreeable burgundy flavor.—Rheinhessen or the Palatinate produces an immense quantity of wine, the yield in favorable seasons averaging 16,000,000 gallons, which is of a medium good quality, its purity and delicacy of taste, and its cheapness, greatly approaching the wines of the Moselle. In bouquet, it not unfrequently surpasses the Moselle. The vineyards occupy a fertile, rising plain, somewhat elevated above the level of the Rhine, and bounded on the north by the Haardt mountains, a northerly extension of the Vosges range. About 25,000 acres are under cultivation. The wines of the first growth are Rupertsberger, Deidesheimer, and Forster; of the second, Dürkheimer, and Königsbach.—Rheinhessen produces wines partaking of the character of those of the Palatinate and Moselle. Well known growths are produced in and around the villages of the Liebfrauen-Stift, near Bingen, a middle-class wine of the Rheingau, the Lachberger and Feuerberg, in the neighborhood; and the wines of the Rheingau, Bodenheim, Oppenheim, Nierstein, and several of which have considerable reputations.

tation, and are often substituted for wines of the Rheingau. The district of Oberingelheim produces much red wine, resembling burgundies of the second and third class, from Burgundy grapes. The produce of the Nahe is nearly related to the middling growths of the Palatinate.—The Bavarian wines, grown in Lower Franconia, in the valley of the Main, are distinguished rather for their body and strength than for their bouquet, and are mostly consumed within the country. The only varieties exported are those produced in the neighborhood of Würzburg, where about 4,500 acres are under cultivation. The best vineyards are the Leiste and the Stein, the products of which are of fine quality and very expensive. Both are situated on the Main, and the former is principally owned by the king of Bavaria, who stores the wine made from the estate in the cellars which underlie the royal castle of Würzburg. In these cellars are more than 280 large casks, some having a capacity of 2,500 gallons. Though considered in the last century indispensable to the proper ripening of wine, they are now but little used. The Leiste wine of good quality is mostly carried to Munich and drunk at court, and only a small quantity enters into trade. The Stein wine, which is also very celebrated, is sold in short-necked bottles of a peculiar shape, called *Bocksbeutel*. Much of the wine passing under this name in England and the United States is the product of the Palatinate, which at Mentz and elsewhere is put into bottles of the shape of the *Bocksbeutel* and sold as Stein.—In Baden a large quantity of third or fourth class wine is produced, the best growth being the white Markgräfler and the Affenthaler, a light, agreeable red wine. The great tun in the castle of Heidelberg was formerly filled with a wine grown in a district known as the Bergstrasse, which commences at Zwingenberg, in the province of Starkenburg, and follows a range of hills to Heidelberg.—More than half of the wine grown in Würtemberg is produced in the valley of the Neckar, and though not of high grade is agreeable to the taste and wholesome. From its changeable color it is termed Schiller.—The general character of the wines grown in the valley of the Moselle is that of thin Rhine wine. They are lighter and less spirituous than those heretofore described, and are noted for an aromatic flavor, which, however, is said to be generally communicated to the wine by mixing with it a tincture of elder flowers, called also the "essence of muscatel," because it resembles the concentrated flavor of the muscatel grape. Messrs. Thudicum and Dupré, in their "Treatise on the Origin, Nature, and Varieties of Wine" (London, 1872), say: "It must be declared with emphasis that there is not a grape of muscatel grown upon the Moselle fit for wine making; that there is not a single barrel of wine made there which naturally has the muscatel flavor; and that

all the wine having the flavor which imitates it is made up with tincture of elder flowers." The better sorts are highly esteemed in Germany for their supposed medicinal properties. The wines held in highest repute are the Brauneberger and Scharzberger, the latter grown on the Saar, a tributary of the Moselle; and scarcely less noted are the Zeltinger, Graacher, Dun, Piesporter Auslese, Josephshoff, Berncastel, Grünhausen, and Scharzhoffberger. The area under cultivation comprises about 23,000 acres, yielding in favorable seasons 160 gallons to the acre.—About 50 years ago sparkling wines were first manufactured in Germany at Esslingen and Heilbronn, from the Neckar grape; and the process has since been so successfully carried on that these wines may be considered in some degree the rivals of champagne. Upward of 2,000,000 bottles of sparkling Moselle and sparkling hock are annually made at Hochheim, Mentz, Coblenz, and other places, much of which, by means of false labels, is sold as champagne, and readily passes for such. The process of manufacture is precisely similar to that employed in making champagne. (See FRANCE, WINES OF.) The seasons of 1871, 1872, and 1873 were the most disastrous known to German viticulturists.

**GERMERSHEIM**, a fortified town of Rhenish Bavaria, at the confluence of the Queich and the Rhine, 7 m. S. W. of Spire; pop. in 1871, 6,223. It has several churches and schools, and an active trade in grain, hemp, flax, and fruits. Ship building and fisheries are carried on, and gold is washed from the sands of the Rhine. Originally a Roman stronghold, the present town was founded by the emperor Rudolph of Hapsburg, who died here in 1201. It formed part of the electoral Palatinate from 1330 to 1622, when it was conquered by Austria. From 1644 to 1650 it was occupied by the French, who retook and devastated the place in 1674 under Turenne. After the death of the elector Charles (1685), the French again claimed possession, whence arose the Germersheim war of succession, which came partly to an end through the treaty of Ryswick (1697), and finally through the arbitration of the pope (1702). It was subsequently the scene of important military operations up to July, 1793, when the French were here defeated by the Austrians. Germersheim having been made a fortress of the German confederation, works have been in progress since 1835, forming together with the fortress of Landau, distant 10 m., and with a tête-de-pont on the right bank of the Rhine, a strong strategical position.

**GEROK**, Karl, a German prelate and poet, born at Vaihingen, Würtemberg, Jan. 30, 1815. He studied at the gymnasium of Stuttgart, held various ecclesiastical offices, and in 1868 was appointed first preacher of the court and chief consistorial councillor. His published sermons have passed through many editions, and his religious poems, including

wine of each year. The quantity of wine annually produced has varied from 25 pieces of 240 gallons each to 60 pieces. The wines of inferior quality, produced in poor years, are sold by auction immediately after the spring racking, and only the select qualities are kept in the cellars of the estate. At the age of four or five years they are bottled, after which they greatly improve in bouquet. The largest yield was in 1857, when 60 pieces, or 14,400 gallons, realized at auction \$60,000. The difficulty of obtaining genuine Schloss-Johannisberger is very great, and large quantities of spurious wine are sold under the name. The first quality has been known to command from \$5 to \$8 a bottle; but the auction wines are much less valuable, and sell for from \$250 to \$1,000 the piece, according to the qualities they possess for mixing.—Next in reputation to the Johannisberger wine, if not its equal, is that produced on the estate of Steinberg, which until 1866 was the property of the dukes of Nassau, but in that year passed into the possession of the crown of Prussia. The Steinberg is a hill 3 m. from the Rhine, the vine-growing portion of which occupies an area not exceeding 60 acres, enclosed by a massive wall of masonry. This, with the mountain barrier in the rear, effectually screens the vineyard from chilling or injurious winds. The estate, which once belonged to the wealthy cloister of Eberbach, includes also a farm of 450 acres, maintained for the sole purpose of producing the manure necessary for the vineyard. The latter has various undulations and hollows, by which it is divided into districts yielding different qualities of wine. The soil is heavier than that of the Schloss Johannisberg, and on this account in warm seasons the ripening of the grape is not as a rule effected before the latter has reached its full maturity. The opposite result is often witnessed in the Johannisberg vineyard. Thus, during the years 1857, 1858, and 1859, which were exceptionally warm, the Steinberg wines showed a marked superiority over those of the Johannisberg. The discovery that the over-ripe grapes yield the best wine was made on this estate about 50 years ago, and since then the vintage has always been very late. In ordinary years there are two or three selections of grapes, from the first of which is made the best wine, the rest hanging 10 or 15 days longer. The annual product of the estate varies from 14,000 to 20,000 gallons, valued at \$350 to \$3,500 the piece, the latter price being paid for the choicest cabinet wines only. The *Auslese* of certain exceptionally fine years has sometimes sold in the cask as high as \$5 a bottle. The ordinary qualities, like those of the Johannisberg wine, are sold annually by auction.—Scarcely inferior to these wines are those produced on the Rüdesheim-Berg and Hinterhaus, which have a southerly exposure, and lie so near the Rhine that the reflection of the sun from the surface of the river greatly facilitates the ripening of the grape. The vine-

yards, comprising an area of about 300 acres, divided among a number of proprietors, are terraced from the base to the summit of the hills, and yield wines of considerable body and fine bouquet, the best qualities of which are high-priced. A short distance below Rüdesheim is Asmannshausen, which yields the very good red wine of the Rheingau. This is produced from the black Burgundy grape known as the *pinéau noir*, whence the wine is also spoken of as a species of Rhenish burgundy. It has a soft and exceedingly delicate flavor, but like the higher class of burgundies suffers from transportation. The wines produced on the estates of Marcobrunn, Hattenheim (first growth), Gräfenberg (first growth), and Geisenheim-Rothenberg, also rank as of the highest quality, and in favorable seasons command enormous prices. Of the second growth of the Rheingau produce, the most esteemed varieties are the Johannisberg-Claus, Vollrath, and Rantenthal-Berg. Among the third growths may be mentioned Hattenheimer, Winkel, Hallgarten, Rüdesheimer, Geisenheimer, Erbach, Elfeld, and Lorch, which may be regarded as the ordinary wines of commerce. In good seasons, and when the best grapes only are selected, these latter growths sometimes reach a high degree of excellence, and command a correspondingly high price.—The banks of the Rhine from Asmannshausen to Coblenz are thickly planted with vineyards, but the situations being for the most part unfavorable, little or no wine of first-rate quality is produced on this part of the river. But in the valley of the little river Ahr, which enters the Rhine about 20 m. below Coblenz, is grown a pale red wine, called the Ahr-Bleichart, having certain strengthening and astringent qualities, and an agreeable burgundy flavor.—Rhenish Bavaria or the Palatinate produces an immense quantity of wine, the yield in favorable seasons reaching 16,000,000 gallons, which is noted for its medium good quality, its purity and freshness of taste, and its cheapness. While never approaching the wines of the Rheingau in bouquet, it not unfrequently surpasses them in richness. The vineyards occupy a fertile, undulating plain, somewhat elevated above the valley of the Rhine, and bounded on the west by the Haardt mountains, a northerly continuation of the Vosges range. About 25,000 acres are under cultivation. The wines of the first growth are Rupertsberger, Deidesheimer, Wachenheimer, and Forster; of the second, Ungstein, Dürkheimer, and Königsbach.—Rhenish Hesse produces wines partaking of the qualities of those of the Palatinate and of the Rheingau. Well known growths are the Liebfrauenstück, produced in and around the convent garden of the Liebfrauen-Stift, near Worms, an agreeable middle-class wine of fine bouquet; the Scherlachberger and Feuerberger of Bingen and its neighborhood; and the wines of Lauenstein, Bodenheim, Oppenheim, Nierstein, and Selchen, several of which have considerable local reputations.

tation, and are often substituted for wines of the Rheingau. The district of Oberingelheim produces much red wine, resembling burgundies of the second and third class, from Burgundy grapes. The produce of the Nahe is nearly related to the middling growths of the Palatinate.—The Bavarian wines, grown in Lower Franconia, in the valley of the Main, are distinguished rather for their body and strength than for their bouquet, and are mostly consumed within the country. The only varieties exported are those produced in the neighborhood of Würzburg, where about 4,500 acres are under cultivation. The best vineyards are the Leiste and the Stein, the products of which are of fine quality and very expensive. Both are situated on the Main, and the former is principally owned by the king of Bavaria, who stores the wine made from the estate in the cellars which underlie the royal castle of Würzburg. In these cellars are more than 280 large casks, some having a capacity of 2,500 gallons. Though considered in the last century indispensable to the proper ripening of wine, they are now but little used. The Leiste wine of good quality is mostly carried to Munich and drunk at court, and only a small quantity enters into trade. The Stein wine, which is also very celebrated, is sold in short-necked bottles of a peculiar shape, called *Bocksbeutel*. Much of the wine passing under this name in England and the United States is the product of the Palatinate, which at Mentz and elsewhere is put into bottles of the shape of the *Bocksbeutel* and sold as Stein.—In Baden a large quantity of third or fourth class wine is produced, the best growth being the white Markgräfler and the Affenthaler, a light, agreeable red wine. The great tun in the castle of Heidelberg was formerly filled with a wine grown in a district known as the Bergstrasse, which commences at Zwingenberg, in the province of Starkenburg, and follows a range of hills to Heidelberg.—More than half of the wine grown in Württemberg is produced in the valley of the Neckar, and though not of high grade is agreeable to the taste and wholesome. From its changeable color it is termed Schiller.—The general character of the wines grown in the valley of the Moselle is that of thin Rhine wine. They are lighter and less spirituous than those heretofore described, and are noted for an aromatic flavor, which, however, is said to be generally communicated to the wine by mixing with it a tincture of elder flowers, called also the "essence of muscatel," because it resembles the concentrated flavor of the muscatel grape. Messrs. Thudicum and Dupré, in their "Treatise on the Origin, Nature, and Varieties of Wine" (London, 1872), say: "It must be declared with emphasis that there is not a grape of muscatel grown upon the Moselle fit for wine making; that there is not a single barrel of wine made there which naturally has the muscatel flavor; and that

all the wine having the flavor which imitates it is made up with tincture of elder flowers." The better sorts are highly esteemed in Germany for their supposed medicinal properties. The wines held in highest repute are the Brauneberger and Scharzberger, the latter grown on the Saar, a tributary of the Moselle; and scarcely less noted are the Zeltinger, Graacher, Dun, Piesporter Auslese, Josephshoff, Berncastel, Grünhausen, and Scharzhoffberger. The area under cultivation comprises about 23,000 acres, yielding in favorable seasons 160 gallons to the acre.—About 50 years ago sparkling wines were first manufactured in Germany at Esslingen and Heilbronn, from the Neckar grape; and the process has since been so successfully carried on that these wines may be considered in some degree the rivals of champagne. Upward of 2,000,000 bottles of sparkling Moselle and sparkling hock are annually made at Hochheim, Mentz, Coblentz, and other places, much of which, by means of false labels, is sold as champagne, and readily passes for such. The process of manufacture is precisely similar to that employed in making champagne. (See FRANCE, WINES OF.) The seasons of 1871, 1872, and 1873 were the most disastrous known to German viticulturists.

**GERMERSHEIM**, a fortified town of Rhenish Bavaria, at the confluence of the Queich and the Rhine, 7 m. S. W. of Spire; pop. in 1871, 6,223. It has several churches and schools, and an active trade in grain, hemp, flax, and fruits. Ship building and fisheries are carried on, and gold is washed from the sands of the Rhine. Originally a Roman stronghold, the present town was founded by the emperor Rudolph of Hapsburg, who died here in 1201. It formed part of the electoral Palatinate from 1330 to 1622, when it was conquered by Austria. From 1644 to 1650 it was occupied by the French, who retook and devastated the place in 1674 under Turenne. After the death of the elector Charles (1685), the French again claimed possession, whence arose the Gernersheim war of succession, which came partly to an end through the treaty of Ryswick (1697), and finally through the arbitration of the pope (1702). It was subsequently the scene of important military operations up to July, 1793, when the French were here defeated by the Austrians. Gernersheim having been made a fortress of the German confederation, works have been in progress since 1835, forming together with the fortress of Landau, distant 10 m., and with a tête-de-pont on the right bank of the Rhine, a strong strategical position.

**GEROK, Karl**, a German prelate and poet, born at Vaihingen, Württemberg, Jan. 30, 1815. He studied at the gymnasium of Stuttgart, held various ecclesiastical offices, and in 1868 was appointed first preacher of the court and chief consistorial councillor. His published sermons have passed through many editions, and his religious poems, including

*Pfingstrosen* (4th ed., 1870) and *Palmblätter* (17th ed., 1871), have made him famous. Besides his poems *Blumen und Sternen* (3d ed., 1870), he published during the Franco-German war of 1870-'71 patriotic effusions under the title of *Deutsche Ostern*.

**GÉRÔME, Jean Léon**, a French painter, born in Vesoul, May 11, 1824. In 1841 he went to Paris and studied under Paul Delaroche, whom he accompanied to Italy. He returned to Paris in 1845, and exhibited his first picture in 1847. For several years afterward he travelled in the East, his journeys furnishing him with numerous subjects for pictures. He obtained medals in 1847, 1848, and 1855, and in the last year received the decoration of the legion of honor. In 1863 he became professor of painting in the school of fine arts, and in 1869 was decorated with the order of the red eagle. He has produced many pictures of the life of the ancients, which have placed him at the head of a school of art designated as the Pompeian or New Greek; and several of his pictures have been criticised as indelicate to the last degree. Among his works are "The Virgin, the Infant Jesus, and St. John," "Bacchus and Cupid," "A Greek Interior," the frieze of the vase commemorative of the London exhibition of 1851, "The Plague at Marseilles," "The Death of St. Jerome," and "A Lioness meeting a Jaguar." His masterpiece in historical art is "The Age of Augustus and the Birth of Jesus Christ," exhibited in 1855, and purchased by the French government. He exhibited in London in 1871 a naked Nubian girl, entitled "To be Sold," and "Cleopatra brought to Caesar in a Basket," the latter inferior to most of his other works. One of his latest pictures, "The Gladiators," was purchased in 1873, by Mr. A. T. Stewart of New York, for 80,000 francs.

**GERONA.** I. A province of Spain, in Catalonia, forming the N. E. extremity of the peninsula, bordering on France and the Mediterranean, and on the provinces of Barcelona and Lérida; area, 2,272 sq. m.; pop. in 1870 (estimated), 325,110. The surface is chiefly covered with the ramifications of the Pyrenees, but fertile valleys frequently intervene. The inhabitants of the interior are mostly engaged in agriculture and cattle rearing; those of the coast in ship building, fishing, and navigation. The principal rivers are the Ter and the Fluvià. Among the towns are Rosas and Figueras, both fortified, Olot, and Ripoll. II. A city (anc. *Gerunda*), capital of the province, at the confluence of the Ter and Oñá, 52 m. N. E. of Barcelona; pop. about 10,000. The chief manufactures are linen and woollen fabrics, paper, soap, earthenware, and hardware. It was captured by Charlemagne, regained by the Moors, and is famous for the sieges it has sustained.

**GERRY, Elbridge**, an American statesman, fifth vice president of the United States, born in Marblehead, Mass., July 17, 1744, died in Washington, Nov. 13, 1814. He graduated at Har-

vard college in 1762, and was elected in 1772 representative from Marblehead to the legislature. He at once became a political leader, and an associate of Samuel Adams, Hancock, and Warren. He was placed on the two most important committees, those of safety and supplies, which sat at Cambridge, on the day preceding the battle of Lexington. In January, 1776, he was elected a delegate to the continental congress, signed the Declaration of Independence, was placed on the most important committees, and was generally chairman of the committee of the treasury till the organization of the treasury board in 1780, of which he became presiding officer. He retired from congress in that year, but resumed his seat in 1783. As delegate to the convention which met in Philadelphia in 1787 to revise the articles of confederation, he refused to sign the constitution proposed, but lent it his support as member of congress after it had received the sanction of the people. He served four successive years in congress, and in 1795 retired to private life, residing in Cambridge, till in 1797 he was appointed to accompany Pinckney and Marshall on a special mission to France. He was invited to remain in Paris, though his associates were ordered to quit France, and he then obtained the evidence and assurances upon which the subsequent commission acted. On his return he was unsuccessfully supported by the democratic party of Massachusetts for the office of governor in 1798, and again in 1801, but was elected after an excited canvas in 1810, and was reelected in 1811. In 1812 he was elected vice president of the United States, but died suddenly in the second year of his term.

**GERSE**, a S. W. department of France, formed from parts of Gascony and Guienne, bordering on the departments of Lot-et-Garonne, Tarn-et-Garonne, Haute-Garonne, Hautes-Pyrénées, Basses-Pyrénées, and Landes; area, 2,425 sq. m.; pop. in 1872, 284,717. The surface is in general hilly. It is watered by the Gers (which rises in Hautes-Pyrénées, and flows N. into the Garonne), Save, Adour, and several other rivers. The most important vegetable products are the cereals, flax, and onions. Fruit is scarce. Large quantities of wine and brandy are made, but of ordinary quality. The minerals are of little consequence, but gypsum and a fusible spar used in making glass and porcelain abound. The only manufactures are brandy, coarse woollens, leather, bricks, glass, and earthenware. It is divided into the arrondissements of Auch, Mirande, Condom, Lectoure, and Lombez. Capital, Auch.

**GERSON, Jean Charles de**, a French theologian, born at Gerson, near Rheims, Dec. 14, 1363, died in Lyons, July 12, 1429. At the age of 14 he went to Paris to study the humanities and theology, and in 1387 he was selected by the university as one of its deputies to the antipope Clement VII. at Avignon upon the controversy concerning the immaculate conception. About 1398 he was made chancellor

of the university of Paris. Charles VI. had just fallen into insanity, and while divisions menaced the state, the church was rent by a schism which produced two and afterward three pretenders to the pontificate. Gerson exerted himself for the reform of morals and the banishment of scholasticism from the university, combated astrology, and resisted the invasion of the pantheistic doctrines which then had their seat in Brabant. When the duke of Orleans was assassinated by the duke of Burgundy in 1407, Gerson denounced the murderer and delivered the funeral oration of his victim. Pursued by John the Fearless, he saw his house pillaged, and was obliged to conceal himself in the vaults of Notre Dame. He was present in the council of Constance as theologian of the bishop of Paris; and, as the council had been convened for the purpose of electing a pope whom all Christendom would acknowledge, he urged the deposition of the two pretenders to the papacy, John XXIII. and Benedict XIII., in a treatise *De Auferibilitate Papæ*. He wished to prove that there are circumstances in which the assembled bishops of the whole church can compel pretenders to the papal dignity to renounce their claim, and depose them if they refuse to abdicate. The schism was at length ended, but Gerson's efforts to check the abuses which reigned in the church were ineffectual; and as civil dissensions did not permit his return to France, he retired to the mountains of Bavaria, where he wrote *De Consolatione Theologia*, and the *Monotessaron*, a harmony of the four Gospels. He returned to his country after a voluntary exile of two years, and found an asylum in a convent. Though one of the most active men of his age, he was also the most mystical of its thinkers. He was the first who sought to give to mysticism the character of a science. He recognized in the soul two classes of faculties: the cognitive or intellectual, whose highest act is simple intuition of divine things; and the affective faculties, whose highest act is ecstatic delight in God. To substitute this mystical philosophy for scholasticism was the aim of his writings. As many manuscripts of the "Imitation of Jesus Christ" bear the name of Gerson, that work is often ascribed to Gerson. (See KEMPIA, THOMAS A.) See *Vie de Gerson* (Paris, 1832); C. Schmidt; *Essai sur Jean Gerson* (Strasbourg, 1839); and R. Thomassy, *Jean Gerson* (Paris, 1843). The best edition of Gerson's works is that of Dupin (5 vols. fol., Antwerp, 1706).

**GERSON BEN JUDAH**, a rabbi of France, distinguished by the appellations *Rabbenu* (our master), *Hazzaken* (the old man), and *Meor haqqolah* (light of the exiled), born in Germany about 960, died about 1030. He wrote a commentary on the Talmud, of which only slight fragments remain, and is celebrated for the introduction of various reforms among the European Jews, including the abolition of polygamy and repudiation, known under the name of "institutions (*gezecroth*) of Rabbenu Gerson."

**GERSTÄCKER, Friedrich**, a German traveller and novelist, born in Hamburg in May, 1816, died in Vienna, May 31, 1872. After a brief term in a commercial school he was apprenticed to a grocer in Cassel; but becoming dissatisfied, he ran away on foot to Bremen, and in the spring of 1837 engaged as cabin boy on board a vessel bound for New York. He led a wandering and adventurous life in the United States for several years, a part of which was spent as a hunter and trapper among the savages of the Indian territory. In 1842 he bought a hotel at Point Coupée, Louisiana; but this having proved a bad speculation, he returned in 1843 to Germany and engaged in literary pursuits, publishing *Streif und Jagdzüge durch die Vereinigten Staaten Nordamerikas* (1844); *Die Regulatoren in Arkansas* (1846); *Mississippibilder* (1847); *Die Flusspiraten des Mississippi* (1848); *Amerikanische Wald- und Strombilder* (1849); and several minor works and translations. In March, 1849, he set out on a journey around the world, during which he visited South America, California, the Hawaiian islands, Australia, and Java, and returned to Germany in 1852, making his residence at Leipsic. An account of this trip was published under the title of *Reisen* (5 vols., 1853-'4). During the succeeding four years he published a number of novels. In 1860 he made an extensive tour through South America, visiting Ecuador, Peru, Chili, Uruguay, and Brazil, and returned home the following year. In 1862 he accompanied Duke Ernest of Gotha to Upper Egypt, Nubia, and Abyssinia, and in 1863 he visited the Central American states. He set out in 1867 on another journey around the world, visiting first the United States, Mexico, and South America. He went thence to the Pacific isles, and after an extended tour returned to Europe, and published a number of novels illustrative of the countries through which he had passed. Some of his later works are: *Neue Reisen durch die Vereinigten Staaten, Mexico, Ecuador, Westindien und Venezuela* (1868); *Die Missionäre* (1868); *Die Blauen und die Gelben* (1870); *Bunter Treiben* (1870); *In Mexico* (1871); *Hamburger Nachrichten* (1871); *Herrn Mahlhübers Reiseabenteuer* (1871). Several of his works have been translated into English.

**GERVINUS, Georg Gottfried**, a German historian and statesman, born in Darmstadt, May 20, 1805, died in Heidelberg, March 18, 1871. He was educated at the university of Heidelberg, afterward spent several years in Italy, and on his return to Heidelberg in 1835 was appointed extraordinary professor. He had already published *Geschichte der Angelsachsen im Überblick* (1830), and *Historische Schriften* (1833), and in 1836 he was appointed professor of history and literature at Göttingen. He had now begun *Die Geschichte der poetischen Nationalliteratur der Deutschen* (1835-'8), which was supplemented by the *Neuere Geschichte*, &c. (1840-'42). In the latest edition (5 vols.,

Leipsic, 1871) these two works are comprised under the general title *Geschichte der deutschen Dichtung*. In them the author traces the development of poetry in its relations to the progress of civilization and of society. He lost his chair at Göttingen in 1837 by signing the famous university protest against the abolition of the Hanoverian constitution. In 1838 he made another journey to Italy, renewed his historical researches at Rome, and returned to Heidelberg, where he became honorary professor in 1844. He now took part in the political affairs of Germany, advocating liberal ideas. In 1847 he was one of the founders of the *Deutsche Zeitung*, the organ of the constitutional party, and in 1848 was elected a member of the Germanic diet, and subsequently of the parliament at Frankfort, and had a prominent part in forming the constitution eventually adopted by the latter assembly. In 1850 he went to England, where he made unsuccessful efforts in behalf of the duchies of Schleswig and Holstein, and on his return to Heidelberg resumed his historical writings. Among his later works are: *Shakspeare* (4 vols., 1849-'50); *Geschichte des neunzehnten Jahrhunderts* (8 vols., 1855-'66, besides an introductory volume published in 1854), beginning with the fall of Napoleon and brought down to the year 1831; *Händel und Shakspeare* (1868); and *Händel's Oratorientexte*, published posthumously by his son in 1873.

GESENIUS, Friedrich Heinrich Wilhelm, a German orientalist, born in Nordhausen, Feb. 3, 1786, died in Halle, Oct. 23, 1842. He studied at the universities of Helmstedt and Göttingen, and was appointed in 1806 *magister legendi* at Göttingen, in 1809 professor of ancient literature in the gymnasium of Heiligenstadt, in 1810 subordinate, and in 1811 ordinary professor of theology in the university of Halle, where he remained to the end of his life. Devoting himself to the study of the Semitic languages, and particularly of the Hebrew, Gesenius founded a new school of Biblical exegesis, chiefly based on an accurate, rational, and historico-critical study of philology. His works are: "Hebrew and Chaldaic Lexicon for the use of the Old Testament" (2 vols., Leipsic, 1810-'12; 4th German ed., 1834; 2d Latin ed., 1846; translated into English by J. W. Gibbs, Andover, 1824, and by Edward Robinson, Boston, 1836; new and greatly enlarged editions, 1850 and 1855); "Elementary Course of the Hebrew Language" (2 vols.), comprising a "Hebrew Grammar" (Halle, 1813; 16th ed. by Rödiger, Leipsic, 1851; translated into English by Moses Stuart, Andover, 1826, and by T. J. Conant, Boston, 1839), and a "Hebrew Reader" (Halle, 1814; several times republished by different editors); "Critical History of the Hebrew Language" (Leipsic, 1815; 2d ed., 1827); *De Pentateuchi Samaritani Origine, Indole et Auctoritate* (Halle, 1815); "Grammatico-critical System of the Hebrew Language" (2 vols., Leipsic, 1827); "Transla-

tion of the Prophet Isaiah, with a Philologico-critical-historical Comment" (3 vols., Leipsic, 1820-'21); *Scripturae Linguaeque Phœnicæ Monumenta* (3 vols., Leipsic, 1837); and *Thesaurus Philologico-criticus Linguae Hebraeae et Chaldaeae Veteris Testamenti* (3 vols., Leipsic, 1829-'53; part of vol. iii. by Rödiger).

GESNER, Konrad von, a Swiss naturalist and philologist, born in Zürich, March 26, 1516, died there, Dec. 13, 1565. He studied at Zürich, Strasburg, Paris, Basel, and Montpellier, and was successively master of a school at Basel, teacher at Lausanne, and practicing physician and professor at Zürich. His first important work was *Bibliotheca Universalis* (Zürich, 1545-'9), containing the titles of all the books then known in Hebrew, Greek, and Latin, with criticisms, summaries, and specimens. In 1555 appeared his *Mithridates de Differentiis Linguarum*, having accounts of 180 ancient and modern languages. His most important work, *Historia Animalium*, published between 1551 and 1556, is a summary of all that was then known of zoology. His *Opera Botanica* (published by Schenckel, Nuremberg, 1753-9) gives particular attention to the flower and the fruit, and suggests the possibility of a classification by means of the organs of fructification.

GESNER, Salomon, a Swiss painter and poet, born in Zürich, April 1, 1780, died there, March 2, 1788. His father attempted in vain to engage him in his own business of bookbinding, and allowed him to follow his inclination for poetry and landscape painting. He resided successively at Berlin, Hamburg, and Zürich, first becoming known by his poem *Die Nacht*, which was followed by *Daphnis*, a pastoral in three cantos, by *Idyllen*, *Der Tod Abels* in prose, some moral tales and dramas, and lectures on landscaping. Some of the engravings with which he illustrated his poems are excellent.

GETA, P. Septimius. See CARACALLA.

GETE, a Thracian tribe mentioned by Herodotus and Thucydides as living S. of the Ister (Danube), and by later writers among the tribes N. of that river. Some critics regard them as identical with the Dacians, others with the Goths. Rawlinson, in his notes on Herodotus, favors the latter opinion, and points to the "striking analogy of the compounds *Manngetæ*, *Thyssagetæ*, and *Tyrigetæ*, to the later names of Visigoths and Ostrogoths."

GETHSEMANE (from Heb. *gath shemen*, oil press), a garden or olive plot near Jerusalem, and across the brook Kedron, to which Jesus with his disciples often repaired, notably on the night of his betrayal. The brook Kedron runs through a deep ravine, parallel with and about 200 yards from the E. wall of Jerusalem. Immediately beyond it rises the steep side of Olivet, which is still cultivated in rude terraces. The garden or olive patch of Gethsemane must have been situated somewhere on the slope. The precise spot is still an open question. There is a modern garden in which

are eight ancient olive trees, with several younger ones, which have been planted or have sprung up from the roots of older trees. This spot was several years ago bought by the Latin church, and laid out in walks and flower beds. In it is pointed out the grotto of the agony, excavated in the rock, the descent to which is by a flight of rudely cut steps. The form of the interior is circular, about 15 ft. in diameter, the roof, supported by pilasters,

Gethsemane.

being perforated to admit light. The Armenian and Greek churches deny that this is the true site of Gethsemane, and they have fixed up in another place a little to the north. Dr. Robinson thinks that the site claimed by the Latins is that believed to be the true one by Eusebius and Jerome, and as likely to be so as any. Dr. Thomson thinks both sites are too near the city, and that Gethsemane was in the secluded valley still further to the northeast.

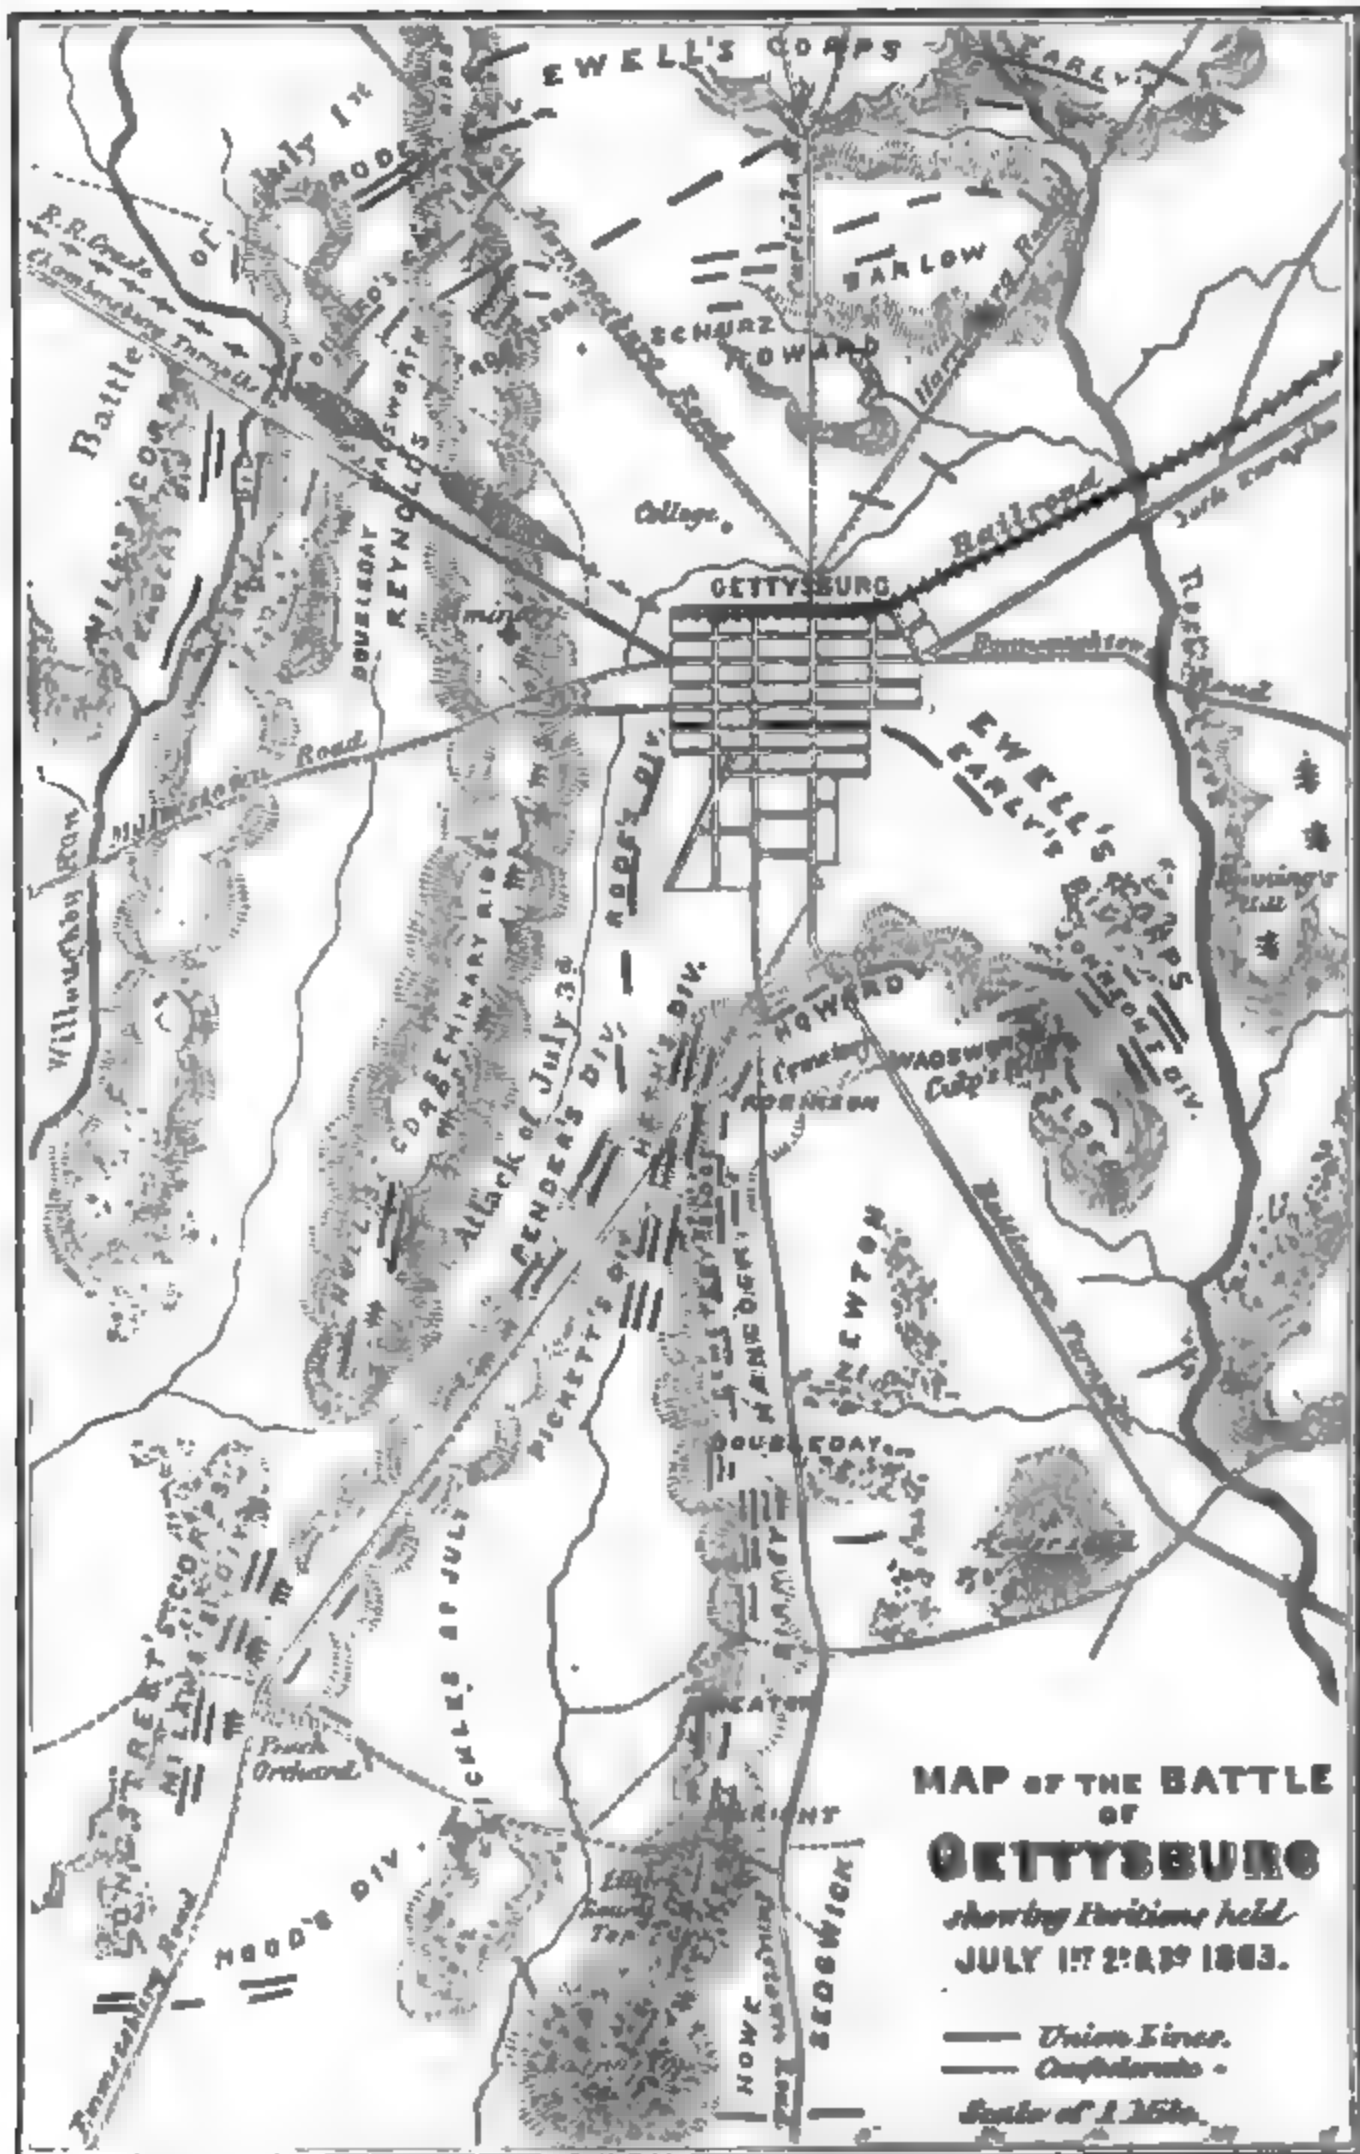

**GETTYSBURG**, a borough and the capital of Adams co., Pennsylvania, situated on elevated ground in a rich farming country, at the terminus of the Susquehanna, Gettysburg, and Potomac railroad, 26 m. S. W. of Harrisburg; pop. in 1870, 3,074. The court house and public offices are commodious brick structures; the residences are generally neat and substantial. The borough is extensively engaged in the manufacture of carriages, is supplied with good water conveyed in iron pipes from a neighboring spring, and has two national banks, a female seminary, two weekly newspapers, a theological quarterly, and eight churches. It is the seat of Pennsylvania col-

lege (Lutheran), founded in 1832, and having in 1871-'2 11 professors and instructors (8 in the preparatory department), 92 collegiate and 37 preparatory students, and libraries containing 18,300 volumes; and of a Lutheran theological seminary, founded in 1825, and having 4 professors and 2 lecturers, 46 students, a library of 10,100 volumes, and an endowment of \$100,000. The buildings belonging to these institutions are large and beautiful edifices. The national cemetery, containing the remains of Union soldiers who fell in the battle of Gettysburg, occupies about 17 acres on Cemetery hill adjacent to the village cemetery, and was dedicated with imposing ceremonies, and an impressive address by President Lincoln, Nov. 19, 1863. A monument occupying the crown of the hill, dedicated July 4, 1868, is 60 ft. high, and is crowned with a statue of Liberty. At the base of the pedestal are four buttresses, surmounted by statues representing War, History, Peace, and Plenty. Around the monument, in semicircular slopes, are arranged the dead, the space being divided by alleys and pathways into 22 sections, one for the regular army, one for the volunteers of each state represented in the battle, and three for the unknown dead. The number of bodies interred here is 3,564, of which 994 have not been identified. Adjoining the national cemetery is a national soldiers' orphans' homestead, founded at the close of the war by benevolent contributions of Sunday schools and individuals, containing usually about 100 orphans. One mile W. of the borough, near the spot where Gen. Reynolds fell on the first day of the battle, are the Gettysburg springs, whose waters, denominated katalysine, have acquired a wide reputation for their medicinal qualities. A fine hotel near by accommodates the patients who resort in large numbers to these springs during the summer. Since the battle Gettysburg has attracted tourists from all parts of the world.

**GETTYSBURG, Battle of**, fought July 1, 2, and 3, 1863, between the Union army of the Potomac under Gen. Meade, and the confederate army of Northern Virginia under Gen. Lee. After the battle of Chancellorsville (May 2-4, 1863), the confederates resolved upon an invasion of the north, believing that a decided success there would bring the war to a speedy close. Their whole disposable force except that in the west was to be employed in this enterprise. Southern Virginia and North Carolina were almost stripped of troops to augment the army of Northern Virginia, and early in June a force of nearly 100,000 men, of whom 15,000 were cavalry, was concentrated in the vicinity of Culpeper. This was nearly the largest and by far the best organized and equipped army which the confederacy ever placed in the field. It was formed into three corps, under Longstreet, Ewell, and A. P. Hill, the cavalry being commanded by Stuart. It began to move slowly down the valley of the Shenandoah, whereupon Hooker, who then

commanded the Union army, broke up his camp opposite Fredericksburg, and moved northward, on a line parallel with that of Lee, the Blue Ridge being between them. Lee endeavored by an ostentatious stretching out of his force to induce Hooker to pass the mountains and assail him. Finding this unavailing, he moved toward the Potomac, Winchester being the point of concentration of all his corps. Milroy, with 10,000 men, had been lying here, where on June 15 he was assailed by the confederate van, and his force dispersed, losing 2,300 prisoners. Raids were then made into Maryland and Pennsylvania, meeting with so little resistance that an invasion in force of Pennsylvania was resolved upon. On the 24th and 25th the Potomac was crossed at two points, almost within sight of the battle field of Antietam. The two columns, uniting at Hagerstown, Md., pressed on toward Chambersburg, Pa. Hooker on the 28th also crossed the river lower down, and headed toward Frederick City, Md. Lee had by this time gone so far from the river as to leave his communications exposed, and Hooker resolved to fall upon these rather than precipitate a general battle. There were at this time 10,000 Union troops at Harper's Ferry, who could be of no use there. Hooker asked that these should be united with his army. The request was refused by Halleck, who was then general-in-chief, and Hooker thereupon sent in his resignation, which was accepted, and on June 28 Meade was appointed in his place. The confederate corps of Ewell had in the mean while reached Carlisle, Pa., and was preparing to advance to Harrisburg, while Longstreet and Hill halted at Chambersburg. The position was now such that Meade by a rapid march could throw his whole force in Lee's rear, isolating him in a hostile country, and cutting off his sources of supply. Lee perceived that the movement northward could be carried no further until he had routed the army which hung menacingly upon his flank and rear; and he resolved to concentrate his whole force in the direction of the enemy, Gettysburg being fixed upon as the place of union. Meade, learning of this movement, resolved to concentrate his columns, which were spread over a wide space, a part under Reynolds being at Gettysburg, and a part under Sedgwick 35 m. southward. The advance was to be drawn back, and the rear brought forward to a point on Pipe creek, 15 m. S. E. of Gettysburg, where Meade resolved to await the attack of the enemy. Lee was wholly ignorant of the position of his enemy; for when he crossed the Potomac, Stuart with the cavalry had been left behind to harass the Union rear, in Virginia, and then to cross the river and rejoin the army at Carlisle. Stuart, crossing at a point below that where Hooker had just crossed, found the enemy between him and Lee, and could reach Carlisle only by making a wide detour; on reaching it, July 1, he found it

evacuated, and the army in movement toward Gettysburg, whither he hastened, but arrived too late to take part in the actions of the first two days.—JULY 1. On the morning of July 1 Hill, whose corps was in the advance, learned that Gettysburg, from which he was distant about 6 m., was occupied by a Union force. Sending back to urge Longstreet to hasten his march, he moved on. In the mean while Reynolds had sent out a cavalry reconnoissance in the direction whence Hill was coming, and the forces came in collision about 2 m. N. W. of Gettysburg. Reynolds sent infantry to the support of his cavalry, and the action opened. He was killed at the beginning of the fight, and the command here devolved upon Howard. At first the Union forces were superior, and they gained decided advantages, taking nearly 1,000 prisoners. But in a few hours nearly the whole of Hill's corps came up from Chambersburg, and Ewell's from Carlisle, both numbering about 50,000, while their opponents were less than half as many. The Union force was driven back in confusion through Gettysburg, losing about 5,000 prisoners. The remainder took up a strong position on Culp's hill, just south of the town. The Union loss in this action was about 10,000, half of whom were killed and wounded. The confederate loss in killed and wounded was probably somewhat greater; in prisoners much less. Meade, who was 15 m. distant, had learned that there was fighting at Gettysburg, and sent Hancock with orders to take command of the force there, and to decide what should be done: for, as it happened, Meade knew nothing of Gettysburg. Hancock decided that this was the place to give battle, and sent back word to Meade to hurry all his troops to the place. Some of these came up during the night, others early in the following morning, and finally, after a march of 35 m., Sedgwick's corps in the afternoon. Lee had in the mean while suspended operations until he could bring up his whole army.—JULY 2. Early in the morning the bulk of the two armies was in position. Southward of Gettysburg, at the distance of a mile, rises Cemetery ridge. It curves first northward, then westward, and finally runs southward, the whole length being about 3 m., the shape being like a fish hook. It rises in places into several craggy hills, each having its own name. That on the extreme south, forming the stem of the fish hook, is Round Top, separated by a ravine from Little Round Top; at the bend of the hook is Cemetery hill; Culp's hill forms the barb. The Union army was posted along the whole line of Cemetery ridge. Opposite this is Seminary ridge, upon which the greater part of Lee's army was posted; Ewell's corps, however, lay at the foot of Culp's hill, 2 m. distant. The forces present or close at hand were about equal, each numbering from 70,000 to 80,000 infantry and artillery. Between the two ridges is a valley in which and on the slope of Cemetery ridge were fought the

actions of July 2 and 3. It is clear from what followed that Lee greatly underestimated the force opposed to him, and he resolved to attack it in its strong position. Longstreet was to assail the Union left at Round Top, while Ewell was to make on the right, at Culp's hill, "a demonstration, to be converted into a real attack should opportunity offer." Meade had intended that his line should be posted on the ridge directly between Round Top and Cemetery hill. But this ridge, in the centre where Sickles was placed, is comparatively low, sinking down into a valley a few hundred yards wide, beyond which rises another wooded crest running diagonally to the former; and Sickles supposed this to be the one which he was to occupy. Before the error could be corrected the confederate attack had begun, and Meade decided to support Sickles in his present position, although it left an unoccupied space between him and Round Top. As it happened, Hood's division of Longstreet's corps struck this opening. Moreover, by some mischance Little Round Top had been left unoccupied, and this was the key to the entire Union position; for if the enemy could seize this, and place a few guns upon it, the whole line would be enfiladed. The confederates perceived this, and began to swarm up the rugged sides. But just in time Warren, who as engineer was examining the line, discovered the error, and brought up a few regiments. They reached the summit just a moment ahead of the enemy, and forced them back. Again and again until nightfall the assault was unsuccessfully renewed. In the mean time the remainder of Longstreet's corps were pressing fiercely upon Sickles, who was soon borne from the field with his leg shattered. His corps made a stubborn resistance, but was forced back until it reached the crest of the ridge, where a new line was formed. The confederates charged this, but were met with a fire from which they recoiled. Hancock, who now commanded the centre, ordered a counter-charge, by which the enemy were driven back to the ridge previously occupied by Sickles, which they continued to hold. Ewell's demonstration on the Union right was delayed until the action on the left was nearly over; but as most of the Union force had been withdrawn from Culp's hill to aid Sickles, he succeeded in effecting a lodgment within the Union intrenchments. The Union loss in this action was fully 10,000, half of which was in Sickles's corps, which lost nearly half its numbers. This action decided nothing; for the ground which the confederates had won on the Union left was never meant to be held by Meade, and he would gladly have withdrawn from it without a fight; and Ewell's foothold on the Union right was of no importance unless it could be followed up. Still the confederates had gained some apparent advantages; and, says Lee, "These partial successes determined me to continue the assault the next day." From what he could then know, he was justified in this; for he had

every reason to suppose that he had encountered the entire Union force, while less than half of his own had been engaged.—JULY 3. Lee's general plan of attack was similar to that of the preceding day. Ewell was to follow to his advantage, while the main attack was to be made on the centre. But early in the morning Meade had taken the offensive against Ewell, and forced him from the foothold which he had gained. By some unexplained accident Lee was never informed of this mishap, by which a third of his force was left out of action, while Meade was at liberty to concentrate his whole strength upon any point which might be assailed. All the morning was spent in preparation. Seminary ridge formed an admirable position for the confederate artillery, and here directly in front of the Union line they placed 120 guns. A great part of Cemetery ridge is so rugged that artillery could not be placed there; so that although Meade had 200 guns, he could use only 80 at a time. At 1 o'clock the confederates opened fire, which was immediately returned. Many of the Union guns were disabled, but their place was supplied by others. The infantry were so well sheltered behind the crest that they suffered little. After two hours, Hunt, the chief of artillery, gradually suspended fire, "in order to see what the enemy were going to do." Lee, supposing that the Union batteries had been silenced and that the infantry must be demoralized, now ordered the grand attack of the day. This was to be made mainly by Pickett's division of Virginia veterans, who had not yet been engaged. They were to be aided by the brigades of Wilcox and Pettigrew. Exclusive of Wilcox, who did not fairly advance, the attacking column numbered about 18,000. Lee had intended to advance his artillery to support the infantry, but found at the last moment that the ammunition was nearly exhausted, and there was no time to replenish it. The column moved swiftly down the slope of the ridge, and across the plain. All the Union batteries, from Round Top to Cemetery hill, opened upon them, ploughing great furrows through their lines, which were closed up as fast as made. The column at first headed for the left of the Union centre, where Doubleday was posted with 2,500 men, a little in advance of the main line and protected by breastworks of rails and stones. To avoid this the column bent to its left and exposed itself to a severe flank fire. Still it pressed on, until Pettigrew's brigade was within 300 yards of Hancock's line, which had reserved its fire. In five minutes the whole brigade was streaming back in wild disorder. Pickett's division pressed steadily on until it reached Gibbon's front line thinly posted behind a low stone wall. They charged straight over this, among the federal batteries, and for a quarter of an hour there was a struggle with pistols and clubbed muskets. The Union troops hurried from all sides and drove the enemy back down the slope, which was completely

commanded by musketry and artillery. To advance, retreat, or stand still was alike impossible. The men flung themselves on the ground, holding up their hands in token of surrender. Of the whole number, not one in four escaped; the others were dead or prisoners. The attacking column being thus utterly routed in the centre, Meade ordered his right to advance and drive back the division of Hood, which had been held in check upon the ridge they had won the preceding day. This was easily done, and many prisoners were captured. The confederate loss this day was about 16,000 in killed, wounded, and prisoners; the Union loss was about 3,000. During the night Lee concentrated his force behind the crest of Seminary ridge, awaiting and probably desiring an attack. In the morning Meade called a council of war, by which it was decided to "remain a day and await the development of the enemy's plan." Before night a heavy storm set in, under cover of which Lee began his retreat to the Potomac, leaving a strong rear guard to defend the passes through the mountains. He reached the river, 40 m. distant, on the 7th. The stream, which he had crossed almost dry-shod a fortnight before, was now swollen by unusually heavy rains and unfordable. A bridge which he had flung across had been destroyed by a cavalry dash from Harper's Ferry, and he had no alternative but to intrench himself and await an attack or the falling of the waters. Meade advanced slowly by a much longer route, and on the 12th came in front of the confederate intrenchments. He called a council of war, which, against his opinion, voted to postpone the attack until reconnoissances had been made. On the evening of the 13th an order was issued for an advance the next morning; but when day broke the enemy had disappeared. A slight bridge had been constructed, and the river had fallen so as to be fordable at a single point. Ewell's corps crossed by the ford, the others by the bridge. The remains of the confederate army stood safe on the other side; and the invasion of the north, upon which so much had been staked, was at an end.—The Union loss at Gettysburg, was 23,190, of whom 2,834 were killed, 13,713 wounded, and 6,643 missing. The confederate loss has never been officially stated; but by the best estimates it was about 36,000, of whom about 5,000 were killed, 23,000 wounded, and 8,000 unwounded prisoners. The entire number of prisoners, wounded and unwounded, was about 14,000.—At almost the same moment when the final action at Gettysburg took place, the negotiations for the surrender of Vicksburg were concluded. These twin disasters mark the epoch of the decline of the confederacy.

**GEYSERS** (Icelandic, *geysa*, to burst forth violently), intermittent hot springs found in various parts of the world. In Iceland the principal geysers are in the S. W. part of the island, about 35 m. N. W. of Hecla, and 70 m. from Reykiavik, the chief town. In a circuit

of about two miles are more than 100 springs which send forth hot water, 50 or more in the space of a few acres. These are on the lower slope of a small hill of trappean rock, and above them in the steeper part of the hill under the cliffs of this rock are banks formed by the incrustations of ancient and now nearly extinct geysers. The springs are of different dimensions, and exhibit various degrees of activity; some are uniformly full and quiet, others are constantly boiling, and others only at intervals, with explosive discharges of water and steam. The vapors rising from them form clouds that are seen miles away. They are attended with sulphurous odors; and the geysers of other localities on the island deposit sulphur derived from the decomposition of the iron pyrites in the clays through which the hot waters penetrate. The chief spouting springs of the group are the Great geyser and the Great and Little Strokr. The Great geyser when quiet presents the appearance of a circular mound of silicious incrustations, enclosing a pool, with sides sloping inward at an average angle of  $13^{\circ}$ , and outward at a mean inclination of  $8^{\circ}$ . The height of the mound is about 20 ft. on the lower side, but only half as much on the upper side. The diameter of the basin varies from 50 to 60 ft., and its average depth is 4 ft. In its centre is the mouth of the vertical tube which connects it with the subterranean passages. This tube is about 9 ft. in diameter at its mouth, and 70 ft. in depth. When the geyser is inactive, the basin is filled to the edge with clear water, which has a mean temperature of  $185^{\circ}$  F. and runs gently down the mound, emitting clouds of steam; but for several hours after an eruption the tube is empty to the depth of 4 or 5 ft. At intervals of about an hour and a half a rumbling noise is heard, and the water heaves up in the centre, throwing an increased quantity over the margin. The great eruptions take place at irregular intervals, sometimes exceeding 30 hours. At these times loud explosions are heard beneath the surface, the water is thrown into violent agitation, it boils furiously, and at last is suddenly sent forth in a succession of jets, which increase in force till they become an immense fountain that is lost to view in the clouds of steam in which it is enveloped. The heights reached by these jets have been variously estimated by different travellers. The lowest estimate is 60 or 70 ft.; that of Von Troil in 1772 is 92 ft.; of Sir John Stanley in 1789, 96 ft.; of Lieut. Ohlsen, a Danish officer, in 1804, determined by a quadrant, 212 ft.; of Sir George Mackenzie in 1810, 90 ft.; and of Henderson in 1815, 150 ft. Later visitors, Lord Dufferin, Mme. Ida Pfeiffer, J. Ross Browne, and others, estimate the height at from 60 to 70 ft. The eruptions appear to be diminishing in force and frequency, and it is not improbable that they will cease altogether before the lapse of another century. The discharge continues only about five minutes, when the geyser subsides to a state of tranquil-

lity. The Great Strokr, so named either from the Icelandic word meaning churn, or from *stroka*, to agitate, is only 300 or 400 ft. from the Great geyser, from which it differs in appearance in being an irregularly formed well, incrustated with silicious deposits, but having no basin at its mouth. Its orifice is about 8 ft. in diameter, diminishing to about 10 in. at the depth of 27 ft.; the whole depth is a little over 44 ft. The water for the greater part of the time is 10 or 12 ft. below the surface, and is continually boiling and seething, but at intervals of about half a day it breaks forth in a great eruption, throwing its water generally from 40 to 60 ft.; but Bunsen, who saw it in 1846, estimates it to be 151 ft. high. By throwing turf or stones into the well of the Strokr, an eruption can be brought on in a few minutes. The Little Strokr exhibits the same phenomena on a smaller scale. In the same vicinity are two large and quiet wells remarkable for their beautifully blue water. These were once active, and one of them is described by an English traveller as the Roaring geyser. It became tranquil immediately after an earthquake in 1789, when the Great Strokr first broke forth. The deposits of silica which accumulate around the geysers are derived from the small amount of this material which is taken up in solution by the hot water. By the analysis of Dr. Black, made upon 10,000 grains (about  $5\frac{1}{2}$  gills), it would appear that the whole amount of solid matter remaining dissolved in the cold water is only a little more than  $\frac{1}{1000}$  of the whole, the quantity examined yielding as follows: soda, 0.95; alumina, 0.48; silica, 5.40; muriate of soda, 2.46; dry sulphate of soda, 1.46; in all, 10.75. An analysis of the geyserite, or solid deposit, made by Forchhammer, gave the following result: silica, 84.43; water, 7.88; alumina, 3.07; iron, 1.91; lime, 0.70; soda and potassa, 0.92; magnesia, 1.06; total, 99.97. As the water evaporates and is chilled, the excess of silica is added to the surface around, filling the interstices of the mosses and grass, and making of these silicious petrifications, while the living plants still thrive and shoot above the strong substance that binds together their roots and stems. Where the waters are found at a temperature of  $98^{\circ}\text{C}$ . ( $208.4^{\circ}\text{F}$ .), M. Descloiseaux observed that the confervia still flourished. The true theory of the cause of geyser eruptions is due to Bunsen. When in Iceland in 1846, he proved by a series of careful experiments that the temperature of the water in the geyser tube varies at different depths, as also at different periods between two eruptions, the changes always taking place in the same manner and with considerable regularity. Immediately before the eruptions there is a maximum temperature at the bottom of the well estimated at  $260.6^{\circ}\text{F}$ ., and a minimum immediately after of  $253.4^{\circ}$ . The temperature of boiling water at the depth reached by the thermometer should be about  $276^{\circ}\text{F}$ . The water therefore in no part of the tube is

hot enough to generate steam  
tions. But the higher you are  
the lower is the temperature  
will boil. If then the column be  
by the generation of steam in the  
channels, the water at the bottom  
near the boiling point, is brought  
where it is sufficiently relieved  
to be converted into steam. The water  
tube is lifted still higher, until the  
condenses by contact with the cooler  
which it imparts its latent heat. Evap-  
densation makes a detonation, the result  
explosion which precedes an eruption  
successive efforts enough of the  
bent column is thrown off to raise  
the water in the tube to the boiling point  
at last the relief from pressure is  
permit the ejection of the contents.  
This ejection continues until all the water  
around the geyser are emptied, and the  
sides until the proper conditions are met  
again. A boiling spring becomes a  
geyser if, in building up an accumulation  
of precipitated mineral, it forms a tube  
of sufficient height and reaches a  
certain pressure of confinement. When  
the tube reaches such an altitude, the water  
below cannot, in consequence of the in-  
creased pressure, reach the top, and the  
eruptions cease and the geyser becomes a  
cistern. It is a singular fact in  
Iceland that no mention is made of geysers  
until they are spoken of by Sveinur  
of Skalholt, in the 17th century; the more  
remarkable, as Ari Frode, a writer  
of the geography and history of Iceland  
the 11th century, spent his youth in the  
mediate vicinity. They bear no evidence  
of having been in operation in this  
district, if not in the exact place where  
are now found, from remote times. The  
geysers of New Zealand are in the  
New Ulster, the most northerly of the  
islands. About the centre of the island, an  
active volcano of Tongariro, and mud  
fountains, and geysers are found in  
1,000 places, exhibiting phenomena more  
remarkable than those in Iceland. The  
water of Lake Taupo boils and is raised  
by subterranean fires, and the tempera-  
ture of its water is about  $212^{\circ}\text{F}$ . In  
it, a valley through which the river  
flows contains a great number of  
having been counted in 6,000. The  
of water are of various kinds. The most  
notably. About half way between  
Taupo and Plenty bay, on the  
little lake of Rotomahana, whose  
temperature, raised by the steam  
which feed it, is about  $78^{\circ}\text{F}$ . The lake  
is surrounded by springs of  
steam, sulphur, and other minerals,  
continually escaping. One of these,  
the Teicahia (the Great Spring), is  
on the N. E. end of the lake, and

It is described by Von Hochstetter as a crater-like excavation, with steep reddish sides 30 to 40 ft. high, which are open toward the sky only. The basin of the spring is about 100 ft. long and 60 wide, and is filled to the brim with clear transparent water, which against the white incrustated sides appears of a beautiful blue color. Immense clouds of steam continually rise from it, obstructing the view of the surface, and the noise of boiling is always heard. At the margin the temperature is 140° F., but in the centre, where the water is usually in a state of ebullition to the height of several feet, it probably reaches the boiling point. The deposit, like that of the Iceland geysers, is silicious, and the incrustations made by the overflow have formed on the slope a series of terraces, from 2 to 6 ft. in height, level and almost as regular as if cut from marble, on each of which are circular basins, abundant with blue water. These terraces, which cover an area of about three acres, have the appearance of a cataract plunging over several shelves, which as it falls is suddenly arrested into stone. Each stage has a small level margin, from which slender stalactites hang down on the next below. At ordinary times but very little water ripples over these terraces, and only the principal discharge on the side forms a hot steaming fall; but sometimes, say the natives, the whole body of water is thrown up in an enormous column, emptying the pool. On the highest stage is an extensive platform, with a number of basins, from 6 ft. deep, the water showing a temperature of from 90° to 110° F. In the middle of the platform rises, close to the brink of the basin, a rock island, about 12 ft. high, covered with mosses and ferns. From it a full view may be had of the interior of the boiling caldron, without danger. The rocks from which these springs derive their silica are rhyolites and rhyolitic tufas, which contain 70 per cent. of it. An analysis of the solid incrustation of the Tetrata, made by Dr. R. W. Raymond, gave the following result: silica, 84.78; iron and organic substances, 12.86; sesquioxide of iron and alumina, 1.27; lime, magnesia, and alkalies, 1.09; total, 100.—In the United States, volcanic boiling springs exist in various localities west of the Rocky mountains.

In the Colorado desert, between lat. 34° and 35°, and lon. 115° and 116°, are remarkable mud volcanoes and boiling springs. The desert at this point is below the level of the sea. The springs cover a space not more than a quarter of a mile square. This area is covered with soft mud, through which water and steam are constantly escaping, with a noise heard at a distance of ten miles. In some the vapor rises steadily, with a sharp hissing sound; in others it bursts forth with a sudden explosion, throwing water and mud to a height of 100 ft. Some of the boiling springs throw up a column of water 20 or 30 ft. Some have cones formed around them, and

some have basins 100 ft. in diameter, in which the blue paste-like mud is ever bubbling and hissing. Many are incrustated with carbonate of lime, others with deposits of sulphur. The steam which rises from them is strongly impregnated with sulphur. Similar springs exist in New Mexico and in some of the other territories.—The so-called geysers of California are in Sonoma county, in a lateral gorge of the valley of Napa, called the "Devil's Cañon," near the Pluton river. The narrow ravine, which is always filled with vapor, is shut in by steep hills, the sides of which, marked with evidences of volcanic action, are smoking with heat and bare of vegetation. A multitude of springs gush out at the base of the rocks. Hot and cold springs, boiling springs, and quiet springs lie within a few feet of each other. They differ also in color, smell, and taste. Some are clear and transparent, others white, yellow, or red with ochre, and still others are of an inky blackness. Some are sulphurous and fetid in odor, and some are charged with alum and salt. The "Steampipe" is an orifice in the hillside, about 8 in. in diameter, from which a volume of steam rises with a continuous roar to a height varying from 50 to 200 ft. In a cavity called the "Witches' Caldron" a mass of black fetid mud is ever bubbling with heat, the vapor from it depositing black flowers of sulphur on the rocks around. The surface of the ground about the springs, which is too hot to walk upon with thin shoes, is covered with the minerals deposited by the waters, among which are sulphur, sulphate of magnesia, sulphate of aluminum, and various salts of iron. These springs, none of which are properly geysers, are about 1,700 ft. above the sea.—The geysers at the head waters of the Yellowstone and Missouri rivers are probably the most wonderful on the globe, even those in Iceland and New Zealand sinking into insignificance when compared with them. The country lying between lat. 48° and 47° N., and lon. 110° and 114° W., comprising portions of the territories of Idaho, Wyoming, and Montana, is dotted with groups of hot springs, the remains of most remarkable volcanic manifestations, which began probably in the tertiary period. Earthquake shocks are still common throughout this region, and at some seasons of the year are very severe. The most of these springs are not geysers, but simply boiling mineral springs and mud volcanoes. The geysers proper are in the N. W. corner of Wyoming territory, on the Fire-Hole river, the middle fork of the Madison, which is one of the three principal sources of the Missouri. The basin in which they are situated was visited first by a party under Cook and Folsom in 1869. In 1870 Gen. Washburne, surveyor general of Montana, explored it with a party, among whom were Lieut. G. O. Doane and N. P. Langford; and in 1871 it was surveyed by Dr. F. V. Hayden, United States geologist, and by Col. J. W. Barlow and Capt. D. P. Heap, of the United States engineer corps. Dr. R. W. Raymond,

United States commissioner of mining statistics, also visited and described the region in the same year. The geysers lie in two large groups, in what are called the upper and lower geyser basins. The lower basin, beginning near the junction of the East and Middle forks of the Madison, comprises an area of about 30 sq. m. The springs are divisible into three classes: 1, those which are constantly boiling; 2, those which are agitated only at particular periods; 3, those which are always tranquil. In the geysers proper the water is usually quiet until a short time before an eruption. Dr. Peale, who examined them in 1871, in connection with Prof. Hayden, divides the springs into seven principal groups. In the first group, at the N. end of the basin, the temperature of 67 springs, occupying a space of about a quarter of a mile wide by two miles long, was recorded. The lowest was 106° F., the highest 198°. The temperature of the air was 50°. Some of these are geysers, projecting the water from 2 to 5 ft., but most of them are simply silicious springs, a few being chalybeate. The second group, which lies 2½ m. further S., nearer the centre of the basin, occupies an area of about

The Thud Geyser.

three fourths of a mile. Sixteen springs here ranged in temperature from 140° to 196°. The temperature of the air was from 55° to 66°. This group is composed principally of geysers, many of them throwing water from 5 to 10 ft. high. The principal one, on the slope of a hill, is about 20 ft. in diameter, with a rim 5 ft. wide and 5 ft. high. The column of water thrown from it is very wide, and reaches the height of 50 ft. Another is named the Thud geyser, from the dull suppressed sound given off as the water rises and recedes. It has a beautiful scalloped rim, with small basins around it. This group of geysers is said to resemble a factory village, the steam rising in jets from more than 100 orifices. The third group lies three fourths of a mile S. E. of the second, at the base of a spur of the mountains, and extending up a ravine about 1,000 yards. They cover a space 500 yards in width. The temperature of 20 springs ranged from 130° to 196°. Near the centre of the group is a small lake, 600 ft. long by 150 wide, on the E. shore of which is a geyser spouting to the height of from 15 to 20 ft. There are three sulphur springs here, the

only ones in the region, and S. E. of the lake is an iron spring. About 1,000 yards further S. is the fourth group, in a ravine about 1½ m. long and 800 yards wide. It contains many springs and geysers, the temperature of 43 of which ranged from 112° to 193°, the temperature of the air being about 60°. The principal geyser is at the mouth of the ravine. Its basin is circular and about 60 ft. in diameter, and its spring, in the centre, from 15 to 20 ft. The water is blue, and is constantly agitated. When in eruption the column is projected 10 ft. high, and is accompanied by immense clouds of steam. Near the upper end of the ravine is a spring around which the deposit is black instead of the usual white. The fifth group, on the banks of the Fire-Hole river, is the largest of all, covering nearly a square mile and comprising a great number of springs and geysers. The temperature of 95 examined ranged from 112° to 196°, the air at the time being 70°. None of them are of much importance. One, from its resemblance to a regular, from 8 to 10 ft. in diameter, is low it, on the bank of the river, where is a geyser, with a crater 3 ft. in diameter. The geyser has a crater like a bowl, about 10 ft. in diameter at the top and 6 ft. at the bottom, in constant ebullition. The basin is a square basin 80 ft. across. The Cavern has a basin 15 ft. in diameter, 20 ft. in depth; the water is of a bluish tint, and of wonderful clearness. The springs of this group are from 2 to 20 or 30 ft. in height, varying from turbid water to clear. They are in a constant state of ebullition, of different colors, being some white, others brown, black, or blue. The sixth group is 2 m. S. W., on the Fire-Hole. They are in a U-shaped like valley, for the temperature of 34 of them ranged from 106° to 198°. One of the principal is called the Caldron, the most obscured by the dense clouds of steam rising from it. The valley of the Fire-Hole is the lower basin. It is not a single geyser, covering an area of about 100 acres. It contains fewer springs than the others, but the exhibited are far more numerous. The springs and geysers are all tending along on the Fire-Hole, the temperature of 106 to 196°, the average temperature of the air being 70°. At the valley, at its mouth, is the Old Faithful, a geyser.

larity; it spouts at intervals of about an hour, throwing a column of water 6 ft. in diameter to a maximum height of 180 ft., and holding it up by a succession of impulses from 4 to 6 minutes. The great mass of the water falls directly back into the basin, flowing over the edges and down the sides in streams. When the action ceases, the water recedes out of sight, and nothing but the occasional hiss of steam is heard until the time approaches for another eruption. Its crater is a conical mound of geyserite about 12 ft. high, measuring at the base 145 by 215 ft. and at the top 54 by

The Giantess.

20 ft. Near it are four extinct geyser cones. On the opposite side of the river are the Beehive and the Giantess. The former is a silicious cone 3 ft. in height, 20 ft. in circumference at the base, and 3 by 4 ft. in diameter at the top, with an oval orifice 3 by 2 ft. in diameter. When in action, which occurs once in about 24 hours, it throws a column of water entirely filling the crater to a height which, says Langford, was found by triangular measurement to be 219 ft. The eruption lasted 18 minutes, and the stream did not deflect more than 4 or 5° from a vertical line. Dr. Hay-

den witnessed three eruptions, which lasted from 4½ to 15 minutes; he measured the height of but one, which was over 100 ft. He describes the column as fan-shaped, and says that no water falls from it, but it is resolved into spray which appears to evaporate as soon as formed. At 200 yards from the Beehive is the Giantess, a large geyser with an oval aperture described by Langford to be 18 by 25 ft. in diameter. The inside of the tube is corrugated and covered with a whitish silicious deposit. When not in action, no water can be seen in its basin, although its sides are visible to the depth of 100 ft., but a gurgling sound can be heard at a great distance below. When an eruption is about to take place, the water rises in the tube with much spluttering and hissing, sending off vast clouds of steam. It will stand sometimes for several minutes within 40 or 50 ft. of the surface, foaming and gurgling, and spouting jets of hot water nearly to its mouth. When it finally bursts forth, it throws up a column of water the full size of its aperture to the height of 60 ft., and through this rise five or six smaller jets, varying from 6 to 15 in. in diameter, to the height of 250 ft. The eruption, which takes place at irregular intervals, continues for about 20 minutes. Dr. Hayden, who examined it in August, 1872, says the basin measures 23½ by 32½ ft. in diameter, and that the water in it, which is level with the rim, is 63 ft. deep. The only eruption witnessed by him lasted 17 minutes, and the maximum height of the water was 39 ft., the steam rising to 69 ft. After the eruption the water sank 20 ft. in the basin. It probably differs in appearance in different seasons. Further down the river on the same side is the Sawmill geyser, which throws a small stream 10 or 15 ft. high almost uninterruptedly. Near it is the Grand geyser, one of the most powerful in the basin. Within a single basin 52 ft. in diameter are two orifices. One, which is oblong, 2½ by 4 ft., has no rim, and is surrounded for the space of 10 ft. by rounded masses of silica, from a few inches to 3 ft. in diameter, looking like spongi-form coral. When not in eruption the water in this spring is quiet and is as clear as crystal. This is the Grand geyser. The second, called the Turban geyser, is 20 ft. from the first. It has a basin of irregular form, 23 by 11 ft. in diameter and 6 ft. deep. The mouth of its tube, which is at one side of the basin, is 4 by 3 ft. wide. This spring, which apparently has no connection with the former, is in a state of agitation as often as once in 20 minutes, and throws its water to the height of from 15 to 25 ft. It is never wholly quiet. The two eruptions of the Grand geyser witnessed by Prof. Hayden's party in 1871 occurred at an interval of 32 hours. In 1872 three eruptions seen by Hayden took place at intervals of 22 and 26½ hours. An eruption is preceded by a rumbling and a shaking of the ground, followed by a column of steam shooting up from the cra-

Leipsic, 1871) these two works are comprised under the general title *Geschichte der deutschen Dichtung*. In them the author traces the development of poetry in its relations to the progress of civilization and of society. He lost his chair at Göttingen in 1837 by signing the famous university protest against the abolition of the Hanoverian constitution. In 1838 he made another journey to Italy, renewed his historical researches at Rome, and returned to Heidelberg, where he became honorary professor in 1844. He now took part in the political affairs of Germany, advocating liberal ideas. In 1847 he was one of the founders of the *Deutsche Zeitung*, the organ of the constitutional party, and in 1848 was elected a member of the Germanic diet, and subsequently of the parliament at Frankfurt, and had a prominent part in forming the constitution eventually adopted by the latter assembly. In 1850 he went to England, where he made unsuccessful efforts in behalf of the duchies of Schleswig and Holstein, and on his return to Heidelberg resumed his historical writings. Among his later works are: *Shakspeare* (4 vols., 1849-'50); *Geschichte des neunzehnten Jahrhunderts* (8 vols., 1855-'66, besides an introductory volume published in 1854), beginning with the fall of Napoleon and brought down to the year 1831; *Händel und Shakspeare* (1868); and *Händel's Oratorientexte*, published posthumously by his son in 1873.

**GESENIUS, Friedrich Heinrich Wilhelm**, a German orientalist, born in Nordhausen, Feb. 3, 1786, died in Halle, Oct. 23, 1842. He studied at the universities of Helmstedt and Göttingen, and was appointed in 1806 *magister legens* at Göttingen, in 1809 professor of ancient literature in the gymnasium of Heiligenstadt, in 1810 subordinate, and in 1811 ordinary professor of theology in the university of Halle, where he remained to the end of his life. Devoting himself to the study of the Semitic languages, and particularly of the Hebrew, Gesenius founded a new school of Biblical exegesis, chiefly based on an accurate, rational, and historico-critical study of philology. His works are: "Hebrew and Chaldaic Lexicon for the use of the Old Testament" (2 vols., Leipsic, 1810-'12; 4th German ed., 1834; 2d Latin ed., 1846; translated into English by J. W. Gibbs, Andover, 1824, and by Edward Robinson, Boston, 1836; new and greatly enlarged editions, 1850 and 1855); "Elementary Course of the Hebrew Language" (2 vols.), comprising a "Hebrew Grammar" (Halle, 1813; 16th ed. by Rödiger, Leipsic, 1851; translated into English by Moses Stuart, Andover, 1826, and by T. J. Conant, Boston, 1839), and a "Hebrew Reader" (Halle, 1814; several times republished by different editors); "Critical History of the Hebrew Language" (Leipsic, 1815; 2d ed., 1827); *De Pentateuchi Samaritani Origine, Idole et Auctoritate* (Halle, 1815); "Grammatico-critical System of the Hebrew Language" (2 vols., Leipsic, 1827); "Transla-

tion of the Prophet Isaiah, with a Philologico-critical-historical Comment" (3 vols., Leipsic, 1820-'21); *Scripturae Linguaeque Phœnicæ Monumenta* (3 vols., Leipsic, 1837); and *Thesaurus Philologico-criticus Linguae Hebraeae et Chaldaeae Veteris Testamenti* (3 vols., Leipsic, 1829-'53; part of vol. iii. by Rödiger).

**GESNER, Konrad von**, a Swiss naturalist and philologist, born in Zürich, March 26, 1516, died there, Dec. 13, 1565. He studied at Zürich, Strasburg, Paris, Basel, and Montpellier, and was successively master of a school at Basel, teacher at Lausanne, and practicing physician and professor at Zürich. His first important work was *Bibliotheca Universalis* (Zürich, 1545-'9), containing the titles of all the books then known in Hebrew, Greek, and Latin, with criticisms, summaries, and specimens. In 1555 appeared his *Mithridates de Differentiis Linguarum*, having accounts of 130 ancient and modern languages. His most important work, *Historia Animalium*, published between 1551 and 1556, is a summary of all that was then known of zoölogy. His *Opera Botanica* (published by Schenckel, Kempten, 1753-'9) gives particular attention to the flower and the fruit, and suggests the possibility of a classification by means of the organs of fructification.

**GESNER, Salomon**, a Swiss painter and poet, born in Zürich, April 1, 1780, died there, March 2, 1788. His father attempted in vain to engage him in his own business of bookbinding, and allowed him to follow his inclination for poetry and landscape painting. He resided successively at Berlin, Hamburg, and Zürich, first becoming known by his poem *Die Nacht*, which was followed by *Daphnia*, a pastoral in three cantos, by *Idyllen*, *Der Tod Abels* in prose, some moral tales and dramas, and lectures on landscaping. Some of the engravings with which he illustrated his poems are excellent.

**GETA, P. Septimius**. See **CARACALLA**.

**GETE**, a Thracian tribe mentioned by Herodotus and Thucydides as living S. of the Ister (Danube), and by later writers among the tribes N. of that river. Some critics regard them as identical with the Dacians, others with the Goths. Rawlinson, in his notes on Herodotus, favors the latter opinion, and points to the "striking analogy of the compounds *Maegetæ*, *Thyssagetæ*, and *Tyrigetæ*, to the later names of Visigoths and Ostrogoths."

**GETHSEMANE** (from Heb. *geth sêman*, oil press), a garden or olive plot near Jerusalem, and across the brook Kedron, to which Jesus with his disciples often repaired, notably on the night of his betrayal. The brook Kedron runs through a deep ravine, parallel with and about 200 yards from the E. wall of Jerusalem. Immediately beyond it rises the steep side of Olivet, which is still cultivated in rude terraces. The garden or olive patch of Gethsemane must have been situated somewhere on the slope. The precise spot is still an open question. There is a modern garden in which

are eight ancient olive trees, with several younger ones, which have been planted or have sprung up from the roots of older trees. This spot was several years ago bought by the Latin church, and laid out in walks and flower beds. In it is pointed out the grotto of the agony, excavated in the rock, the descent to which is by a flight of rudely cut steps. The form of the interior is circular, about 15 ft. in diameter, the roof, supported by pilasters,

Gethsemane.

being perforated to admit light. The Armenian and Greek churches deny that this is the true site of Gethsemane, and they have fixed upon another place a little to the north. Dr. Robinson thinks that the site claimed by the Latins is that believed to be the true one by Eusebius and Jerome, and as likely to be so as any. Dr. Flinn thinks both sites are too near the city, and that Gethsemane was in the secluded valley still further to the northeast.

**GETTYSBURG**, a borough and the capital of Adams co., Pennsylvania, situated on elevated ground in a rich farming country, at the terminus of the Susquehanna, Gettysburg, and Potomac railroad, 36 m. S. W. of Harrisburg; pop. in 1870, 3,074. The court house and public offices are commodious brick structures, the residences are generally neat and substantial. The borough is extensively engaged in the manufacture of carriages, is supplied with good water conveyed in iron pipes from a neighboring spring, and has two national banks, a female seminary, two weekly newspapers, a free school quarterly, and eight churches. It is the seat of Pennsylvania col-

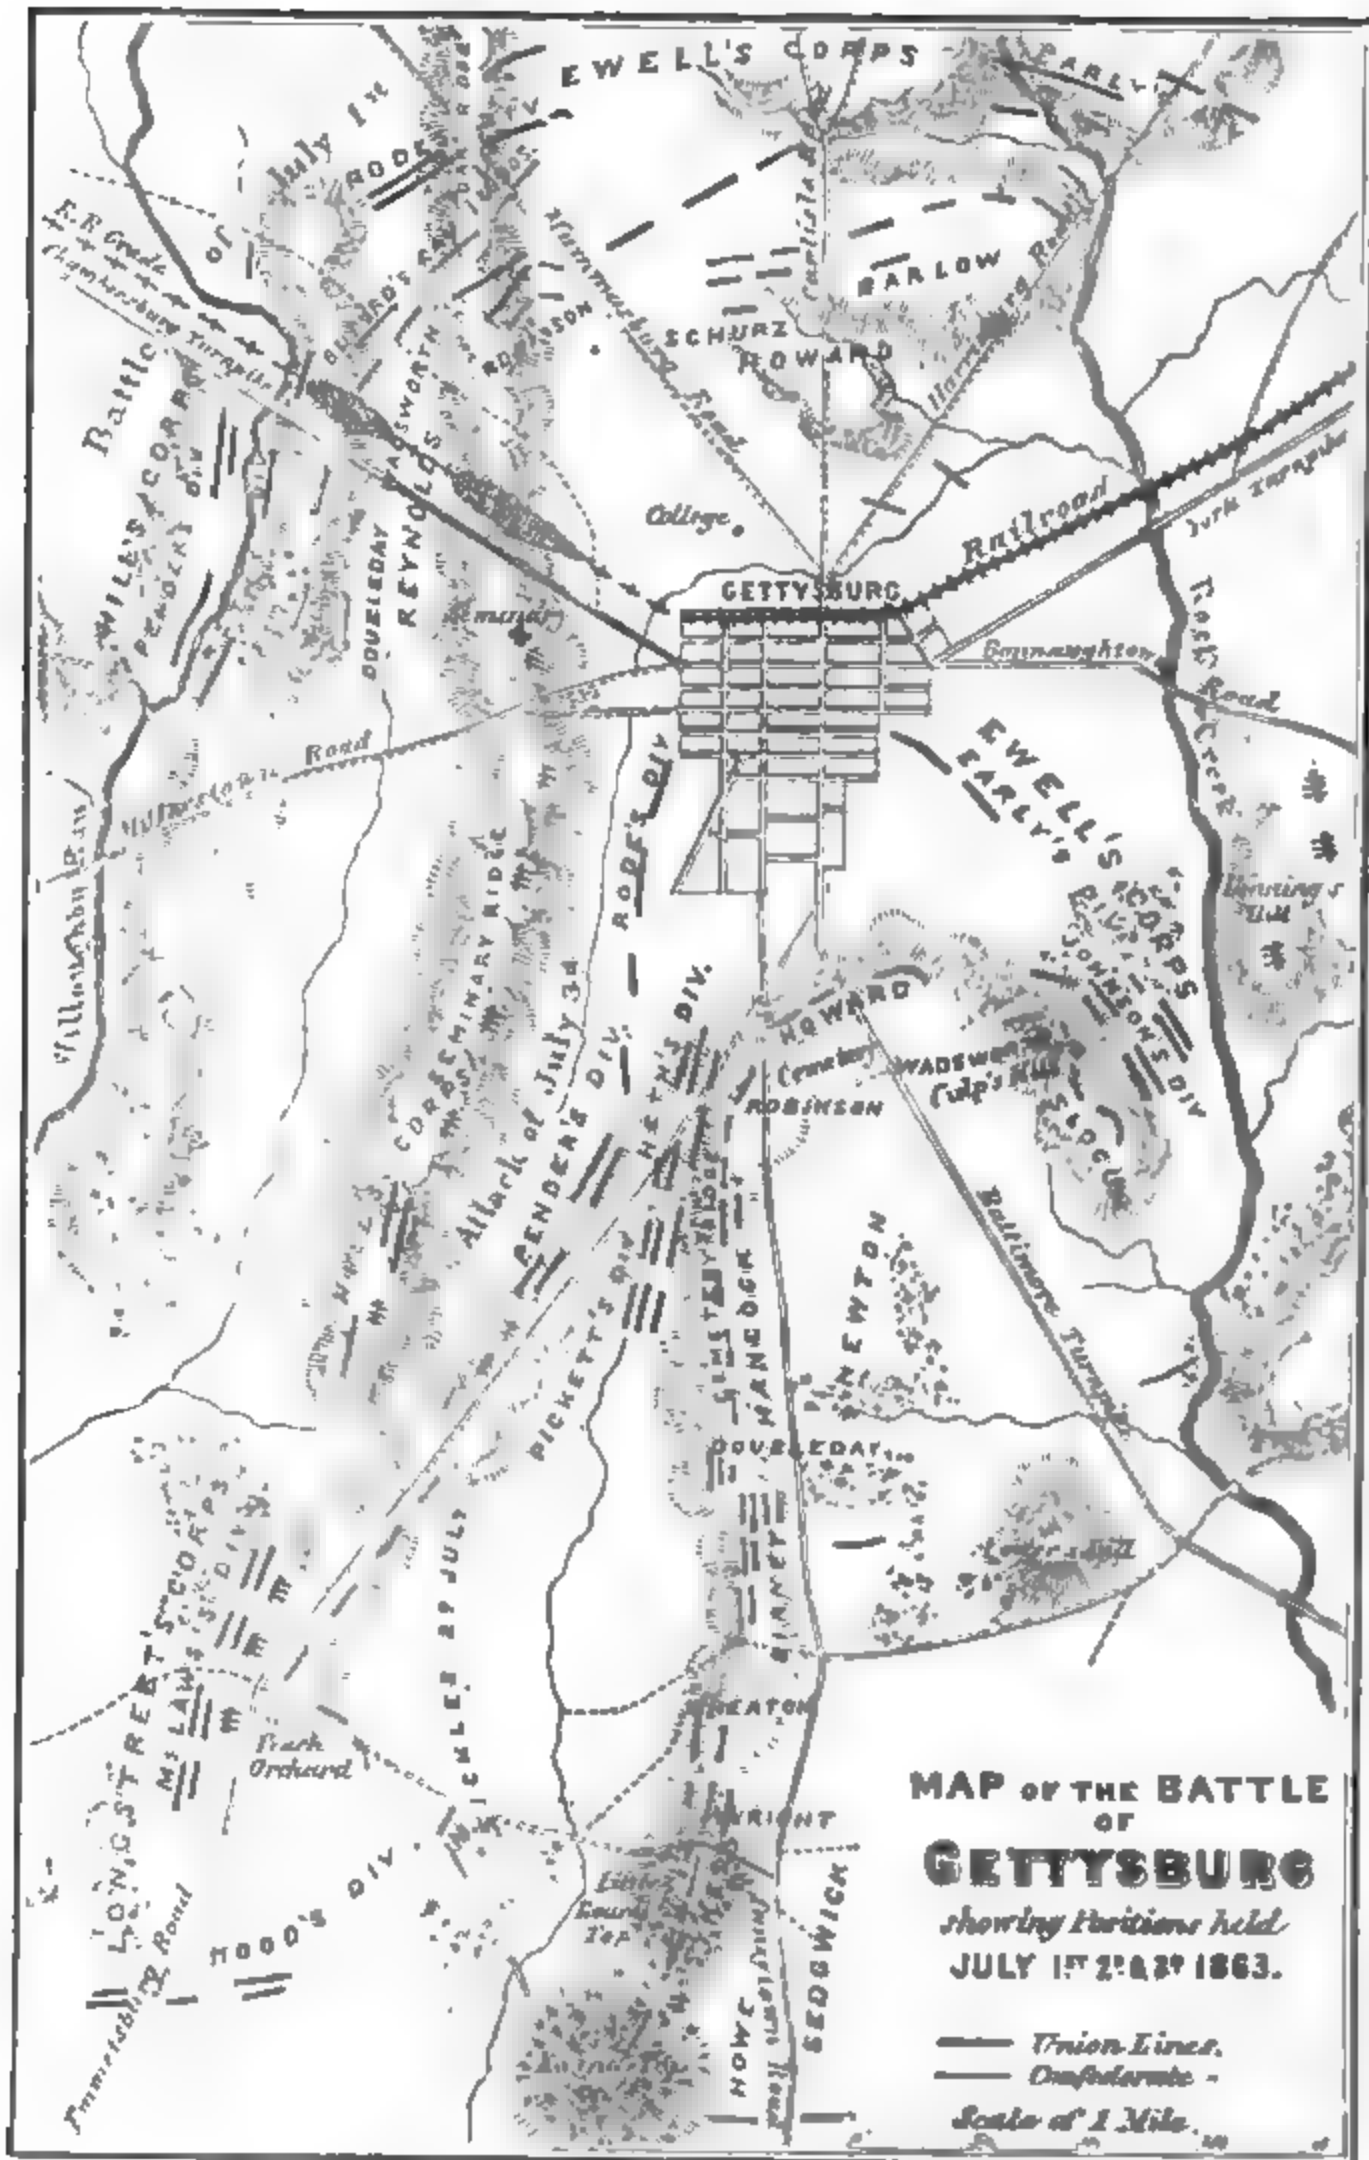

lege (Lutheran), founded in 1832, and having in 1871-'2 11 professors and instructors (3 in the preparatory department), 92 collegiate and 37 preparatory students, and libraries containing 18,300 volumes; and of a Lutheran theological seminary, founded in 1825, and having 4 professors and 2 lecturers, 46 students, a library of 10,100 volumes, and an endowment of \$100,000. The buildings belonging to these institutions are large and beautiful edifices. The national cemetery, containing the remains of Union soldiers who fell in the battle of Gettysburg, occupies about 17 acres on Cemetery hill adjacent to the village cemetery, and was dedicated with imposing ceremonies, and an impressive address by President Lincoln, Nov. 19, 1863. A monument occupying the crown of the hill, dedicated July 4, 1868, is 60 ft. high, and is crowned with a statue of Liberty. At the base of the pedestal are four buttresses, surmounted by statues representing War, History, Peace, and Plenty. Around the monument, in semicircular slopes, are arranged the dead, the space being divided by alleys and pathways into 22 sections, one for the regular army, one for the volunteers of each state represented in the battle, and three for the unknown dead. The number of bodies interred here is 3,564, of which 994 have not been identified. Adjoining the national cemetery is a national soldiers' orphans' homestead, founded at the close of the war by benevolent contributions of Sunday schools and individuals, containing usually about 100 orphans. One mile W. of the borough, near the spot where Gen. Reynolds fell on the first day of the battle, are the Gettysburg springs, whose waters, denominated katalysine, have acquired a wide reputation for their medicinal qualities. A fine hotel near by accommodates the patients who resort in large numbers to these springs during the summer. Since the battle Gettysburg has attracted tourists from all parts of the world.

**GETTYSBURG, Battle of**, fought July 1, 2, and 3, 1863, between the Union army of the Potomac under Gen. Meade, and the confederate army of Northern Virginia under Gen. Lee. After the battle of Chancellorsville (May 2-4, 1863), the confederates resolved upon an invasion of the north, believing that a decided success there would bring the war to a speedy close. Their whole disposable force except that in the west was to be employed in this enterprise. Southern Virginia and North Carolina were almost stripped of troops to augment the army of Northern Virginia, and early in June a force of nearly 100,000 men, of whom 15,000 were cavalry, was concentrated in the vicinity of Culpeper. This was nearly the largest and by far the best organized and equipped army which the confederacy ever placed in the field. It was formed into three corps, under Longstreet, Ewell, and A. P. Hill, the cavalry being commanded by Stuart. It began to move slowly down the valley of the Shenandoah, whereupon Hooker, who then

commanded the Union army, broke up his camp opposite Fredericksburg, and moved northward, on a line parallel with that of Lee, the Blue Ridge being between them. Lee endeavored by an ostentatious stretching out of his force to induce Hooker to pass the mountains and assail him. Finding this unavailing, he moved toward the Potomac, Winchester being the point of concentration of all his corps. Milroy, with 10,000 men, had been lying here, where on June 15 he was assailed by the confederate van, and his force dispersed, losing 2,300 prisoners. Raids were then made into Maryland and Pennsylvania, meeting with so little resistance that an invasion in force of Pennsylvania was resolved upon. On the 24th and 25th the Potomac was crossed at two points, almost within sight of the battle field of Antietam. The two columns, uniting at Hagerstown, Md., pressed on toward Chambersburg, Pa. Hooker on the 28th also crossed the river lower down, and headed toward Frederick City, Md. Lee had by this time gone so far from the river as to leave his communications exposed, and Hooker resolved to fall upon these rather than precipitate a general battle. There were at this time 10,000 Union troops at Harper's Ferry, who could be of no use there. Hooker asked that these should be united with his army. The request was refused by Halleck, who was then general-in-chief, and Hooker thereupon sent in his resignation, which was accepted, and on June 28 Meade was appointed in his place. The confederate corps of Ewell had in the meanwhile reached Carlisle, Pa., and was preparing to advance to Harrisburg, while Longstreet and Hill halted at Chambersburg. The position was now such that Meade by a rapid march could throw his whole force in Lee's rear, isolating him in a hostile country, and cutting off his sources of supply. Lee perceived that the movement northward could be carried no further until he had routed the army which hung menacingly upon his flank and rear; and he resolved to concentrate his whole force in the direction of the enemy, Gettysburg being fixed upon as the place of union. Meade, learning of this movement, resolved to concentrate his columns, which were spread over a wide space, a part under Reynolds being at Gettysburg, and a part under Sedgwick 35 m. southward. The advance was to be drawn back, and the rear brought forward to a point on Pipe creek, 15 m. S. E. of Gettysburg, where Meade resolved to await the attack of the enemy. Lee was wholly ignorant of the position of his enemy; for when he crossed the Potomac, Stuart with the cavalry had been left behind to harass the Union rear, in Virginia, and then to cross the river and rejoin the army at Carlisle. Stuart, crossing at a point below that where Hooker had just crossed, found the enemy between him and Lee, and could reach Carlisle only by making a wide detour; on reaching it, July 1, he found it

evacuated, and the army in movement toward Gettysburg, whither he hastened, but arrived too late to take part in the actions of the first two days.—JULY 1. On the morning of July 1 Hill, whose corps was in the advance, learned that Gettysburg, from which he was distant about 6 m., was occupied by a Union force. Sending back to urge Longstreet to hasten his march, he moved on. In the meanwhile Reynolds had sent out a cavalry reconnoissance in the direction whence Hill was coming, and the forces came in collision about 2 m. N. W. of Gettysburg. Reynolds sent infantry to the support of his cavalry, and the action opened. He was killed at the beginning of the fight, and the command here devolved upon Howard. At first the Union forces were superior, and they gained decided advantages, taking nearly 1,000 prisoners. But in a few hours nearly the whole of Hill's corps came up from Chambersburg, and Ewell's from Carlisle, both numbering about 50,000, while their opponents were less than half as many. The Union force was driven back in confusion through Gettysburg, losing about 5,000 prisoners. The remainder took up a strong position on Culp's hill, just south of the town. The Union loss in this action was about 10,000, half of whom were killed and wounded. The confederate loss in killed and wounded was probably somewhat greater; in prisoners much less. Meade, who was 15 m. distant, had learned that there was fighting at Gettysburg, and sent Hancock with orders to take command of the force there, and to decide what should be done: for, as it happened, Meade knew nothing of Gettysburg. Hancock decided that this was the place to give battle, and sent back word to Meade to hurry all his troops to the place. Some of these came up during the night, others early in the following morning, and after a march of 35 m., Sedgwick's corps arrived in the afternoon. Lee had in the meanwhile suspended operations until he could bring his whole army.—JULY 2. Early in the morning the bulk of the two armies were drawn up Southward of Gettysburg, at a point about 1 mile, rises Cemetery ridge. It runs in a northward, then westward, and then southward, the whole length of the ridge being in the shape of a fish hook. It divides into several craggy hills, each with a name. That on the extreme west, at the stem of the fish hook, is known as Round Top, and is separated by a ravine from Little Round Top, at the bend of the hook is Cemetery ridge. The Union army was drawn up along the whole line of Cemetery ridge, opposite this is Seminary ridge, and the greater part of Lee's army was drawn up on Seminary ridge, the cavalry corps, however, lay at the foot of the ridge, 2 m. distant. The forces present on July 2 were about equal, each having about 70,000 to 80,000 infantry. The distance between the two ridges is a mile, and on the slope of Cemetery ridge

actions of July 2 and 3. It is clear from what followed that Lee greatly underestimated the force opposed to him, and he resolved to attack it in its strong position. Longstreet was to assail the Union left at Round Top, while Ewell was to make on the right, at Culp's hill, "a demonstration, to be converted into a real attack should opportunity offer." Meade had intended that his line should be posted on the ridge directly between Round Top and Cemetery hill. But this ridge, in the centre where Sickles was placed, is comparatively low, sinking down into a valley a few hundred yards wide, beyond which rises another wooded crest running diagonally to the former; and Sickles supposed this to be the one which he was to occupy. Before the error could be corrected the confederate attack had begun, and Meade decided to support Sickles in his present position, although it left an unoccupied space between him and Round Top. As it happened, Hood's division of Longstreet's corps struck this opening. Moreover, by some mischance Little Round Top had been left unoccupied, and this was the key to the entire Union position; for if the enemy could seize this, and place a few guns upon it, the whole line would be enfiladed. The confederates perceived this, and began to swarm up the rugged sides. But just in time Warren, who as engineer was examining the line, discovered the error, and brought up a few regiments. They reached the summit just a moment ahead of the enemy, and forced them back. Again and again until nightfall the assault was unsuccessfully renewed. In the mean time the remainder of Longstreet's corps were pressing fiercely upon Sickles, who was soon borne from the field with his leg shattered. His corps made a stubborn resistance, but was forced back until it reached the crest of the ridge, where a new line was formed. The confederates charged this, but were met with a fire from which they recoiled. Hancock, who now commanded the centre, ordered a counter-charge, by which the enemy were driven back to the ridge previously occupied by Sickles, which they continued to hold. Ewell's demonstration on the Union right was delayed until the action on the left was nearly over; but as most of the Union force had been withdrawn from Culp's hill to aid Sickles, he succeeded in effecting a lodgment within the Union intrenchments. The Union loss in this action was fully 10,000, half of which was in Sickles's corps, which lost nearly half its numbers. This action decided nothing; for the ground which the confederates had won on the Union left was never meant to be held by Meade, and he would gladly have withdrawn from it without a fight; and Ewell's foothold on the Union right was of no importance unless it could be followed up. Still the confederates had gained some apparent advantages; and, says Lee, "These partial successes determined me to continue the assault the next day." From what he could then know, he was justified in this; for he had

every reason to suppose that he had encountered the entire Union force, while less than half of his own had been engaged.—JULY 3. Lee's general plan of attack was similar to that of the preceding day. Ewell was to follow up his advantage, while the main attack was to be made on the centre. But early in the morning Meade had taken the offensive against Ewell and forced him from the foothold which he had gained. By some unexplained accident Lee was never informed of this mishap, by which a third of his force was left out of action, while Meade was at liberty to concentrate his whole strength upon any point which might be assailed. All the morning was spent in preparation. Seminary ridge formed an admirable position for the confederate artillery, and here directly in front of the Union line they placed 120 guns. A great part of Cemetery ridge is so rugged that artillery could not be placed there; so that although Meade had 200 guns, he could use only 80 at a time. At 1 o'clock the confederates opened fire, which was immediately returned. Many of the Union guns were disabled, but their place was supplied by others. The infantry were so well sheltered behind the crest that they suffered little. After two hours, Hunt, the chief of artillery, gradually suspended fire, "in order to see what the enemy were going to do." Lee, supposing that the Union batteries had been silenced and that the infantry must be demoralized, now ordered the grand attack of the day. This was to be made mainly by Pickett's division of Virginia veterans, who had not yet been engaged. They were to be aided by the brigades of Wilcox and Pettigrew. Exclusive of Wilcox, who did not fairly advance, the attacking column numbered about 18,000. Lee had intended to advance his artillery to support the infantry, but found at the last moment that the ammunition was nearly exhausted, and there was no time to replenish it. The column moved swiftly down the slope of the ridge, and across the plain. All the Union batteries, from Round Top to Cemetery hill, opened upon them, ploughing great furrows through their lines, which were closed up as fast as made. The column at first headed for the left of the Union centre, where Doubleday was posted with 2,500 men, a little in advance of the main line and protected by breastworks of rails and stones. To avoid this the column bent to its left and exposed itself to a severe flank fire. Still it pressed on, until Pettigrew's brigade was within 300 yards of Hancock's line, which had reserved its fire. In five minutes the whole brigade was streaming back in wild disorder. Pickett's division pressed steadily on until it reached Gibbon's front line thinly posted behind a low stone wall. They charged straight over this, among the federal batteries, and for a quarter of an hour there was a struggle with pistols and clubbed muskets. The Union troops hurried from all sides and drove the enemy back down the slope, which was completely

commanded by musketry and artillery. To advance, retreat, or stand still was alike impossible. The men flung themselves on the ground, holding up their hands in token of surrender. Of the whole number, not one in four escaped; the others were dead or prisoners. The attacking column being thus utterly routed in the centre, Meade ordered his right to advance and drive back the division of Hood, which had been held in check upon the ridge they had won the preceding day. This was easily done, and many prisoners were captured. The confederate loss this day was about 16,000 in killed, wounded, and prisoners; the Union loss was about 3,000. During the night Lee concentrated his force behind the crest of Seminary ridge, awaiting and probably desiring an attack. In the morning Meade called a council of war, by which it was decided to "remain a day and await the development of the enemy's plan." Before night a heavy storm set in, under cover of which Lee began his retreat to the Potomac, leaving a strong rear guard to defend the passes through the mountains. He reached the river, 40 m. distant, on the 7th. The stream, which he had crossed almost dry-shod a fortnight before, was now swollen by unusually heavy rains and unfordable. A bridge which he had flung across had been destroyed by a cavalry dash from Harper's Ferry, and he had no alternative but to intrench himself and await an attack or the falling of the waters. Meade advanced slowly by a much longer route, and on the 12th came in front of the confederate intrenchments. He called a council of war, which, against his opinion, voted to postpone the attack until reconnoissances had been made. On the evening of the 13th an order was issued for an advance the next morning; but when day broke the enemy had disappeared. A slight bridge had been constructed, and the river had fallen so as to be fordable at a single point. Ewell's corps crossed by the ford, the others by the bridge. The remains of the confederate army stood safe on the other side; and the invasion of the north, upon which so much had been staked, was at an end.—The Union loss at Gettysburg, was 23,190, of whom 2,834 were killed, 13,713 wounded, and 6,643 missing. The confederate loss has never been officially stated; but by the best estimates it was about 36,000, of whom about 5,000 were killed, 23,000 wounded, and 8,000 unwounded prisoners. The entire number of prisoners, wounded and unwounded, was about 14,000.—At almost the same moment when the final action at Gettysburg took place, the negotiations for the surrender of Vicksburg were concluded. These twin disasters mark the epoch of the decline of the confederacy.

**GEYSERS** (Icelandic, *geysa*, to burst forth violently), intermittent hot springs found in various parts of the world. In Iceland the principal geysers are in the S. W. part of the island, about 35 m. N. W. of Hecla, and 70 m. from Reykiavik, the chief town. In a circuit

of about two miles are more than 100 springs which send forth hot water, 50 or more in the space of a few acres. These are on the lower slope of a small hill of trappean rock, and above them in the steeper part of the hill under the cliffs of this rock are banks formed by the incrustations of ancient and now nearly extinct geysers. The springs are of different dimensions, and exhibit various degrees of activity; some are uniformly full and quiet, others are constantly boiling, and others only at intervals, with explosive discharges of water and steam. The vapors rising from them form clouds that are seen miles away. They are attended with sulphurous odors; and the geysers of other localities on the island deposit sulphur derived from the decomposition of the iron pyrites in the clays through which the hot waters penetrate. The chief spouting springs of the group are the Great geyser and the Great and Little Strokr. The Great geyser when quiet presents the appearance of a circular mound of silicious incrustations, enclosing a pool, with sides sloping inward at an average angle of  $13^{\circ}$ , and outward at a mean inclination of  $8^{\circ}$ . The height of the mound is about 20 ft. on the lower side, but only half as much on the upper side. The diameter of the basin varies from 50 to 60 ft., and its average depth is 4 ft. In its centre is the mouth of the vertical tube which connects it with the subterranean passages. This tube is about 9 ft. in diameter at its mouth, and 70 ft. in depth. When the geyser is inactive, the basin is filled to the edge with clear water, which has a mean temperature of  $185^{\circ}$  F. and runs gently down the mound, emitting clouds of steam; but for several hours after an eruption the tube is empty to the depth of 4 or 5 ft. At intervals of about an hour and a half a rumbling noise is heard, and the water heaves up in the centre, throwing an increased quantity over the margin. The great eruptions take place at irregular intervals, sometimes exceeding 30 hours. At these times loud explosions are heard beneath the surface, the water is thrown into violent agitation, it boils furiously, and at last is suddenly sent forth in a succession of jets, which increase in force till they become an immense fountain that is lost to view in the clouds of steam in which it is enveloped. The heights reached by these jets have been variously estimated by different travellers. The lowest estimate is 60 or 70 ft.; that of Von Troil in 1772 is 92 ft.; of Sir John Stanley in 1789, 96 ft.; of Lieut. Ohlsen, a Danish officer, in 1804, determined by a quadrant, 212 ft.; of Sir George Mackenzie in 1810, 90 ft.; and of Henderson in 1815, 150 ft. Later visitors, Lord Dufferin, Mme. Ida Pfeiffer, J. Ross Browne, and others, estimate the height at from 60 to 70 ft. The eruptions appear to be diminishing in force and frequency, and it is not improbable that they will cease altogether before the lapse of another century. The discharge continues only about five minutes, when the geyser subsides to a state of tranquil-

lity. The Great Strokr, so named either from the Icelandic word meaning churn, or from *stroka*, to agitate, is only 300 or 400 ft. from the Great geyser, from which it differs in appearance in being an irregularly formed well, incrustated with silicious deposits, but having no basin at its mouth. Its orifice is about 8 ft. in diameter, diminishing to about 10 in. at the depth of 27 ft.; the whole depth is a little over 44 ft. The water for the greater part of the time is 10 or 12 ft. below the surface, and is continually boiling and seething, but at intervals of about half a day it breaks forth in a great eruption, throwing its water generally from 40 to 60 ft.; but Bunsen, who saw it in 1846, estimates it to be 151 ft. high. By throwing turf or stones into the well of the Strokr, an eruption can be brought on in a few minutes. The Little Strokr exhibits the same phenomena on a smaller scale. In the same vicinity are two large and quiet wells remarkable for their beautifully blue water. These were once active, and one of them is described by an English traveller as the Roaring geyser. It became tranquil immediately after an earthquake in 1789, when the Great Strokr first broke forth. The deposits of silica which accumulate around the geysers are derived from the small amount of this material which is taken up in solution by the hot water. By the analysis of Dr. Black, made upon 10,000 grains (about  $5\frac{1}{2}$  gills), it would appear that the whole amount of solid matter remaining dissolved in the cold water is only a little more than  $\frac{1}{1000}$  of the whole, the quantity examined yielding as follows: soda, 0.95; alumina, 0.48; silica, 5.40; muriate of soda, 2.46; dry sulphate of soda, 1.46; in all, 10.75. An analysis of the geyserite, or solid deposit, made by Forchhammer, gave the following result: silica, 84.43; water, 7.88; alumina, 3.07; iron, 1.91; lime, 0.70; soda and potassa, 0.92; magnesia, 1.06; total, 99.97. As the water evaporates and is chilled, the excess of silica is added to the surface around, filling the interstices of the mosses and grass, and making of these silicious petrifications, while the living plants still thrive and shoot above the strong substance that binds together their roots and stems. Where the waters are found at a temperature of  $98^{\circ}\text{C}$ . ( $208.4^{\circ}\text{F}$ .), M. Descloiseaux observed that the confervæ still flourished. The true theory of the cause of geyser eruptions is due to Bunsen. When in Iceland in 1846, he proved by a series of careful experiments that the temperature of the water in the geyser tube varies at different depths, as also at different periods between two eruptions, the changes always taking place in the same manner and with considerable regularity. Immediately before the eruptions there is a maximum temperature at the bottom of the well estimated at  $260.6^{\circ}\text{F}$ ., and a minimum immediately after of  $253.4^{\circ}$ . The temperature of boiling water at the depth reached by the thermometer should be about  $276^{\circ}\text{F}$ . The water therefore in no part of the tube is

hot enough to generate steam under the conditions. But the higher you ascend in the tube the lower is the temperature at which it will boil. If then the column be thrown up by the generation of steam in the underground channels, the water at the bottom, which is near the boiling point, is brought to a point where it is sufficiently relieved from pressure to be converted into steam. The water tube is lifted still higher, until the steam condenses by contact with the cooler water, which it imparts its latent heat. Each condensation makes a detonation, the successive efforts enough of the superincumbent column is thrown off to raise the water in the tube to the boiling point, at last the relief from pressure permit the ejection of the contents of the tube. This ejection continues until all the water around the geyser are emptied, which subsides until the proper conditions are again. A boiling spring becomes a geyser if, in building up around itself a column of precipitated mineral, it forms a vertical tube of sufficient height and regularity to contain pressure of confined water; when the tube reaches such an altitude that the water below cannot, in consequence of increased pressure, reach the boiling point, eruptions cease and the geyser becomes a cistern. It is a singular fact in Iceland that no mention is made of geysers until they are spoken of by Svenson, of Skalholt, in the 17th century; and the more remarkable, as Ari Frode, a geographer of the 11th century, spent his youth in the immediate vicinity. They bear no resemblance of having been in one district, if not in the same district, are now found, from the geysers of New Zealand to New Ulster, the mountainous country of the north. About the centre of the active volcano of Tonga, mud fountains, and geysers, 1,000 places, exhibiting phenomena more remarkable than those of Lake Taupo, are found by subterranean fires, the temperature of its water is about  $160^{\circ}\text{F}$ . it, a valley through which the water flows contains a great number of having been counted in one valley of water are of various heights. About half way between Taupo and Plenty bay, a little lake of Rotomahana, whose temperature, which feed it, is about  $78^{\circ}\text{F}$ . surrounded by steam, sulphurous, continually escaping. Of these, the Tatarata, N. E. end of the

level. It is described by Von Hochstetter as a crater-like excavation, with steep reddish sides, 30 to 40 ft. high, which are open toward the lake only. The basin of the spring is about 80 ft. long and 60 wide, and is filled to the brim with clear transparent water, which against the white incrustated sides appears of a beautiful blue color. Immense clouds of steam continually rise from it, obstructing the view of the surface, and the noise of boiling is always audible. At the margin the temperature is 183° F., but in the centre, where the water is continually in a state of ebullition to the height of several feet, it probably reaches the boiling point. The deposit, like that of the Iceland springs, is silicious, and the incrustations made by the overflow have formed on the slope a system of terraces, from 2 to 6 ft. in height, as white and almost as regular as if cut from marble, on each of which are circular basins, resplendent with blue water. These terraces, which cover an area of about three acres, have the appearance of a cataract plunging over natural shelves, which as it falls is suddenly turned into stone. Each stage has a small raised margin, from which slender stalactites hang down on the next below. At ordinary times but very little water ripples over these terraces, and only the principal discharge on the side forms a hot steaming fall; but sometimes, say the natives, the whole body of water is thrown up in an enormous column, emptying the pool. On the highest stage is an extensive platform, with a number of basins, from 5 to 6 ft. deep, the water showing a temperature of from 90° to 110° F. In the middle of this platform rises, close to the brink of the main basin, a rock island, about 12 ft. high, covered with mosses and ferns. From it a full view may be had of the interior of the boiling caldron, without danger. The rocks from which these springs derive their silica are rhyolites and rhyolithic tufas, which contain over 70 per cent. of it. An analysis of the solidified incrustation of the Tetarata, made by Mayer, gave the following result: silica, 84.78; water and organic substances, 12.86; sesquioxide of iron and alumina, 1.27; lime, magnesia, and alkalis, 1.09; total, 100.—In the United States, volcanic boiling springs exist in numerous localities west of the Rocky mountains. In the Colorado desert, between lat. 33° and 34°, and lon. 115° and 116°, are remarkable mud volcanoes and boiling springs. The desert at this point is below the level of the sea. The springs cover a space not more than a quarter of a mile square. This area is covered with soft mud, through which water and steam are constantly escaping, with a noise audible at a distance of ten miles. In some places the vapor rises steadily, with a sharp hissing sound; in others it bursts forth with a loud explosion, throwing water and mud to the height of 100 ft. Some of the boiling springs throw up a column of water 20 or 30 ft.; some have cones formed around them, and

some have basins 100 ft. in diameter, in which the blue paste-like mud is ever bubbling and hissing. Many are incrustated with carbonate of lime, others with deposits of sulphur. The steam which rises from them is strongly impregnated with sulphur. Similar springs exist in New Mexico and in some of the other territories.—The so-called geysers of California are in Sonoma county, in a lateral gorge of the valley of Napa, called the "Devil's Cañon," near the Pluton river. The narrow ravine, which is always filled with vapor, is shut in by steep hills, the sides of which, marked with evidences of volcanic action, are smoking with heat and bare of vegetation. A multitude of springs gush out at the base of the rocks. Hot and cold springs, boiling springs, and quiet springs lie within a few feet of each other. They differ also in color, smell, and taste. Some are clear and transparent, others white, yellow, or red with ochre, and still others are of an inky blackness. Some are sulphurous and fetid in odor, and some are charged with alum and salt. The "Steampipe" is an orifice in the hillside, about 8 in. in diameter, from which a volume of steam rises with a continuous roar to a height varying from 50 to 200 ft. In a cavity called the "Witches' Caldron" a mass of black fetid mud is ever bubbling with heat, the vapor from it depositing black flowers of sulphur on the rocks around. The surface of the ground about the springs, which is too hot to walk upon with thin shoes, is covered with the minerals deposited by the waters, among which are sulphur, sulphate of magnesia, sulphate of aluminum, and various salts of iron. These springs, none of which are properly geysers, are about 1,700 ft. above the sea.—The geysers at the head waters of the Yellowstone and Missouri rivers are probably the most wonderful on the globe, even those in Iceland and New Zealand sinking into insignificance when compared with them. The country lying between lat. 43° and 47° N., and lon. 110° and 114° W., comprising portions of the territories of Idaho, Wyoming, and Montana, is dotted with groups of hot springs, the remains of most remarkable volcanic manifestations, which began probably in the tertiary period. Earthquake shocks are still common throughout this region, and at some seasons of the year are very severe. The most of these springs are not geysers, but simply boiling mineral springs and mud volcanoes. The geysers proper are in the N. W. corner of Wyoming territory, on the Fire-Hole river, the middle fork of the Madison, which is one of the three principal sources of the Missouri. The basin in which they are situated was visited first by a party under Cook and Folsom in 1869. In 1870 Gen. Washburne, surveyor general of Montana, explored it with a party, among whom were Lieut. G. C. Doane and N. P. Langford; and in 1871 it was surveyed by Dr. F. V. Hayden, United States geologist, and by Col. J. W. Barlow and Capt. D. P. Heap, of the United States engineer corps. Dr. R. W. Raymond,

lity. The Great Strokr, so named either from the Icelandic word meaning churn, or from *stroka*, to agitate, is only 300 or 400 ft. from the Great geyser, from which it differs in appearance in being an irregularly formed well, incrustated with silicious deposits, but having no basin at its mouth. Its orifice is about 8 ft. in diameter, diminishing to about 10 in. at the depth of 27 ft.; the whole depth is a little over 44 ft. The water for the greater part of the time is 10 or 12 ft. below the surface, and is continually boiling and seething, but at intervals of about half a day it breaks forth in a great eruption, throwing its water generally from 40 to 60 ft.; but Bunsen, who saw it in 1846, estimates it to be 151 ft. high. By throwing turf or stones into the well of the Strokr, an eruption can be brought on in a few minutes. The Little Strokr exhibits the same phenomena on a smaller scale. In the same vicinity are two large and quiet wells remarkable for their beautifully blue water. These were once active, and one of them is described by an English traveller as the Roaring geyser. It became tranquil immediately after an earthquake in 1789, when the Great Strokr first broke forth. The deposits of silica which accumulate around the geysers are derived from the small amount of this material which is taken up in solution by the hot water. By the analysis of Dr. Black, made upon 10,000 grains (about  $5\frac{1}{2}$  gills), it would appear that the whole amount of solid matter remaining dissolved in the cold water is only a little more than  $\frac{1}{1000}$  of the whole, the quantity examined yielding as follows: soda, 0.95; alumina, 0.48; silica, 5.40; muriate of soda, 2.46; dry sulphate of soda, 1.46; in all, 10.75. An analysis of the geyserite, or solid deposit, made by Forchhammer, gave the following result: silica, 84.43; water, 7.88; alumina, 3.07; iron, 1.91; lime, 0.70; soda and potassa, 0.92; magnesia, 1.06; total, 99.97. As the water evaporates and is chilled, the excess of silica is added to the surface around, filling the interstices of the mosses and grass, and making of these silicious petrifications, while the living plants still thrive and shoot above the strong substance that binds together their roots and stems. Where the waters are found at a temperature of  $98^{\circ}$  C. ( $208.4^{\circ}$  F.), M. Descloiseaux observed that the confervæ still flourished. The true theory of the cause of geyser eruptions is due to Bunsen. When in Iceland in 1846, he proved by a series of careful experiments that the temperature of the water in the geyser tube varies at different depths, as also at different periods between two eruptions, the changes always taking place in the same manner and with considerable regularity. Immediately before the eruptions there is a maximum temperature at the bottom of the well estimated at  $260.6^{\circ}$  F., and a minimum immediately after of  $253.4^{\circ}$ . The temperature of boiling water at the depth reached by the thermometer should be about  $276^{\circ}$  F. The water therefore in no part of the tube is

hot enough to generate steam under the conditions. But the higher you ascend in the tube the lower is the temperature at which it will boil. If then the column be thrown up by the generation of steam in the underground channels, the water at the bottom, which is near the boiling point, is brought to a height where it is sufficiently relieved from pressure to be converted into steam. The water in the tube is lifted still higher, until the steam condenses by contact with the cooler water, which it imparts its latent heat. Evaporation and condensation makes a detonation, the subterranean explosion which precedes an eruption. Successive efforts enough of the bent column is thrown off to raise the water in the tube to the boiling point, at last the relief from pressure is permitted the ejection of the contents of the tube. This ejection continues until all the water around the geyser are emptied, when it subsides until the proper conditions are established again. A boiling spring becomes a geyser if, in building up around it a tube of precipitated mineral, it forms a vessel of sufficient height and regularity to maintain a certain pressure of confined water; and when the tube reaches such an altitude that the water below cannot, in consequence of the increased pressure, reach the boiling point, eruptions cease and the geyser becomes a cistern. It is a singular fact in the history of Iceland that no mention is made of geysers until they are spoken of by Snorri of Skalholt, in the 17th century; the more remarkable, as Ari Frode, a geographer of the 11th century, spent his youth in the immediate vicinity. They bear evidence of having been in existence in that district, if not in the exact spot where they are now found, from remote periods. The geysers of New Zealand are in the North Island, the most remarkable being at New Ulster, the most remarkable being at Taupo. About the centre of the North Island is the active volcano of Tongariro, which is surrounded by mud fountains, and geysers. In the North Island, 1,000 places, exhibit geysers, more remarkable than those of Iceland. The water of Lake Taupo boils and is raised by subterranean fires, and the temperature of its water is about  $170^{\circ}$  F. In the North Island, it, a valley through which the Taupo River flows contains a great number of geysers, having been counted in one group. The eruptions of water are of various heights, and are very regular. About half way between Taupo and Plenty bay, on the North Island, is the little lake of Rotomahana, covered with mud, whose temperature, raised by subterranean fires, which feed it, is about  $78^{\circ}$  F. It is surrounded by springs of steam, sulphurous gases, continually escaping. One of these, the Tatarata, is on the N. E. end of the lake.

level. It is described by Von Hochstetter as a crater-like excavation, with steep reddish sides, 30 to 40 ft. high, which are open toward the lake only. The basin of the spring is about 80 ft. long and 60 wide, and is filled to the brim with clear transparent water, which against the white incrustated sides appears of a beautiful blue color. Immense clouds of steam continually rise from it, obstructing the view of the surface, and the noise of boiling is always audible. At the margin the temperature is  $183^{\circ}$  F., but in the centre, where the water is continually in a state of ebullition to the height of several feet, it probably reaches the boiling point. The deposit, like that of the Iceland springs, is silicious, and the incrustations made by the overflow have formed on the slope a system of terraces, from 2 to 6 ft. in height, as white and almost as regular as if cut from marble, on each of which are circular basins, resplendent with blue water. The surface of the ground about the springs, which is too hot to walk upon with thin shoes, is covered with the minerals deposited by the waters, among which are sulphur, sulphate of magnesia, sulphate of aluminum, and various salts of iron. These springs, none of which are properly geysers, are about 1,700 ft. above the sea.—The geysers at the head waters of the Yellowstone and Missouri rivers are probably the most wonderful on the globe, even those in Iceland and New Zealand sinking into insignificance when compared with them. The country lying between lat.  $43^{\circ}$  and  $47^{\circ}$  N., and lon.  $110^{\circ}$  and  $114^{\circ}$  W., comprising portions of the territories of Idaho, Wyoming, and Montana, is dotted with groups of hot springs, the remains of most remarkable volcanic manifestations, which began probably in the tertiary period. Earthquake shocks are still common throughout this region, and at some seasons of the year are very severe. The most of these springs are not geysers, but simply boiling mineral springs and mud volcanoes. The geysers proper are in the N. W. corner of Wyoming territory, on the Fire-Hole river, the middle fork of the Madison, which is one of the three principal sources of the Missouri. The basin in which they are situated was visited first by a party under Cook and Folsom in 1869. In 1870 Gen. Washburne, surveyor general of Montana, explored it with a party, among whom were Lieut. G. C. Doane and N. P. Langford; and in 1871 it was surveyed by Dr. F. V. Hayden, United States geologist, and by Col. J. W. Barlow and Capt. D. P. Heap, of the United States engineer corps. Dr. R. W. Raymond,

United States commissioner of mining statistics, also visited and described the region in the same year. The geysers lie in two large groups, in what are called the upper and lower geyser basins. The lower basin, beginning near the junction of the East and Middle forks of the Madison, comprises an area of about 30 sq. m. The springs are divisible into three classes: 1, those which are constantly boiling; 2, those which are agitated only at particular periods; 3, those which are always tranquil. In the geysers proper the water is usually quiet until a short time before an eruption. Dr. Peale, who examined them in 1871, in connection with Prof. Hayden, divides the springs into seven principal groups. In the first group, at the N. end of the basin, the temperature of 67 springs, occupying a space of about a quarter of a mile wide by two miles long, was recorded. The lowest was 106° F., the highest 198°. The temperature of the air was 50°. Some of these are geysers, projecting the water from 2 to 5 ft., but most of them are simply silicious springs, a few being chalybeate. The second group, which lies 2½ m. further S., nearer the centre of the basin, occupies an area of about

The Thud Geyser.

three fourths of a mile. Sixteen springs here ranged in temperature from 140° to 196°. The temperature of the air was from 55° to 66°. This group is composed principally of geysers, many of them throwing water from 5 to 10 ft. high. The principal one, on the slope of a hill, is about 20 ft. in diameter, with a rim 5 ft. wide and 5 ft. high. The column of water thrown from it is very wide, and reaches the height of 50 ft. Another is named the Thud geyser, from the dull suppressed sound given off as the water rises and recedes. It has a beautiful scalloped rim, with small basins around it. This group of geysers is said to resemble a factory village, the steam rising in jets from more than 100 orifices. The third group lies three fourths of a mile S. E. of the second, at the base of a spur of the mountains, and extending up a ravine about 1,000 yards. They cover a space 500 yards in width. The temperature of 20 springs ranged from 130° to 196°. Near the centre of the group is a small lake, 600 ft. long by 150 wide, on the E. shore of which is a geyser spouting to the height of from 15 to 20 ft. There are three sulphur springs here, the

only ones in the region, and S. E. of the lake is an iron spring. About 1,000 yards further S. is the fourth group, in a ravine about 1½ m. long and 300 yards wide. It contains many springs and geysers, the temperature of 43 of which ranged from 112° to 193°, the temperature of the air being about 60°. The principal geyser is at the mouth of the ravine. Its basin is circular and about 60 ft. in diameter, and its spring, in the centre, from 15 to 30 ft. The water is blue, and is constantly agitated. When in eruption the column is projected 100 ft. high, and is accompanied by immense clouds of steam. Near the upper end of the ravine is a spring around which the deposit is black instead of the usual white. The fifth group, on the banks of the Fire-Hole river, is the largest of all, covering nearly a square mile and comprising a great number of springs and geysers. The temperature of 95 examined ranged from 112° to 196°, the air at the time being 70°. None of them are of much importance. One, from its resemblance to a shell is named the Conch spring; its basin is triangular, from 8 to 10 ft. in diameter. A little below it, on the bank of the river, there is a fine geyser, with a crater 8 ft. high. The Hen geyser has a crater like a horn, about a foot in diameter at the top and 5 ft. at the base; it is in constant ebullition. The Bath spring has a square basin 30 ft. across, of unknown depth. The Cavern has a basin 15 by 20 ft. wide and 20 ft. in depth; the water is of a bluish tint, and of wonderful clearness. The springs of this group are from one to two to 20 or 30 ft. in diameter, and are varying from turbid white to black, and are in a constant state of ebullition. They are of different colors, being white, yellow, brown, black, or blue. The sixth group is 3 m. S. W., on a small valley, the Fire-Hole. They are in a like valley, for the most part, the temperature of 34 of the group ranged from 106° to 198°. One of them is named the Caldron, the most obscured by the dense clouds rising from it. The upper geyser is named the valley of the same river, and the lower basin. It is not so large, covering an area of only about 100 acres; it contains fewer springs, but the springs and geysers are more numerous, tending along on both sides of the valley, at its mouth. The temperature of 106 of the group ranged from 106° to 196°, the average temperature of the air being 70°. The Old Faithful, a geyser

larity; it spouts at intervals of about an hour, throwing a column of water 6 ft. in diameter to a maximum height of 130 ft., and holding it up by a succession of impulses from 4 to 6 minutes. The great mass of the water falls directly back into the basin, flowing over the edges and down the sides in streams. When the action ceases, the water recedes out of sight, and nothing but the occasional hiss of steam is heard until the time approaches for another eruption. Its crater is a conical mound of geyserite about 12 ft. high, measuring at the base 145 by 215 ft. and at the top 54 by

The Giantess.

20 ft. Near it are four extinct geyser cones. On the opposite side of the river are the Beehive and the Giantess. The former is a silicious cone 3 ft. in height, 20 ft. in circumference at the base, and 3 by 4 ft. in diameter at the top, with an oval orifice 3 by 2 ft. in diameter. When in action, which occurs once in about 24 hours, it throws a column of water entirely filling the crater to a height which, says Langford, was found by triangular measurement to be 219 ft. The eruption lasted 18 minutes, and the stream did not deflect more than 4 or 5° from a vertical line. Dr. Hay-

den witnessed three eruptions, which lasted from 4½ to 15 minutes; he measured the height of but one, which was over 100 ft. He describes the column as fan-shaped, and says that no water falls from it, but it is resolved into spray which appears to evaporate as soon as formed. At 200 yards from the Beehive is the Giantess, a large geyser with an oval aperture described by Langford to be 18 by 25 ft. in diameter. The inside of the tube is corrugated and covered with a whitish silicious deposit. When not in action, no water can be seen in its basin, although its sides are visible to the depth of 100 ft., but a gurgling sound can be heard at a great distance below. When an eruption is about to take place, the water rises in the tube with much spluttering and hissing, sending off vast clouds of steam. It will stand sometimes for several minutes within 40 or 50 ft. of the surface, foaming and gurgling, and spurring jets of hot water nearly to its mouth. When it finally bursts forth, it throws up a column of water the full size of its aperture to the height of 60 ft., and through this rise five or six smaller jets, varying from 6 to 15 in. in diameter, to the height of 250 ft. The eruption, which takes place at irregular intervals, continues for about 20 minutes. Dr. Hayden, who examined it in August, 1872, says the basin measures 23½ by 32½ ft. in diameter, and that the water in it, which is level with the rim, is 63 ft. deep. The only eruption witnessed by him lasted 17 minutes, and the maximum height of the water was 39 ft., the steam rising to 69 ft. After the eruption the water sank 20 ft. in the basin. It probably differs in appearance in different seasons. Further down the river on the same side is the Sawmill geyser, which throws a small stream 10 or 15 ft. high almost uninterruptedly. Near it is the Grand geyser, one of the most powerful in the basin. Within a single basin 52 ft. in diameter are two orifices. One, which is oblong, 2½ by 4 ft., has no rim, and is surrounded for the space of 10 ft. by rounded masses of silica, from a few inches to 3 ft. in diameter, looking like spongi-form coral. When not in eruption the water in this spring is quiet and is as clear as crystal. This is the Grand geyser. The second, called the Turban geyser, is 20 ft. from the first. It has a basin of irregular form, 23 by 11 ft. in diameter and 6 ft. deep. The mouth of its tube, which is at one side of the basin, is 4 by 3 ft. wide. This spring, which apparently has no connection with the former, is in a state of agitation as often as once in 20 minutes, and throws its water to the height of from 15 to 25 ft. It is never wholly quiet. The two eruptions of the Grand geyser witnessed by Prof. Hayden's party in 1871 occurred at an interval of 32 hours. In 1872 three eruptions seen by Hayden took place at intervals of 22 and 26½ hours. An eruption is preceded by a rumbling and a shaking of the ground, followed by a column of steam shooting up from the cra-

geysers in the United States, see report of Lieut. G. C. Doane (1871), and the fifth and sixth annual reports of the "United States Geological Survey of the Territories," by F. V. Hayden (1872 and 1873).

**GFRÖRER, August Friedrich**, a German historian, born in Calw, March 5, 1803, died in Carlsbad, July 10, 1861. He studied theology at Tübingen from 1821 to 1825, was appointed in 1828 tutor in the theological seminary of that city, in 1830 librarian at Stuttgart, and in 1846 professor of history in the university of Freiburg. His first work, *Philo und die jüdisch-alexandrinische Theosophie* (2 vols., Stuttgart, 1831), was written from the critical standpoint of the Tübingen school; but while preparing his *Geschichte des Urchristenthums* (3 vols., 1838), he changed his views, and arrived at length, during the publication of his *Allgemeine Kirchengeschichte* (4 vols., 1841-'6), at the opinion that the Roman Catholic church is the true church of Christ; but he did not join that communion till 1853. Besides the works already mentioned, he wrote *Gustav Adolf, König von Schweden* (2 vols., 1835-'7); *Geschichte der ost- und westfränkischen Karolinger* (2 vols., Freiburg, 1858); *Urgeschichte des menschlichen Geschlechts* (2 vols., Schaffhausen, 1855); *Papst Gregor VII. und sein Zeitalter* (7 vols., 1859-'61); *Geschichte des 18. Jahrhunderts* (edited by Weiss, 3 vols., 1862-'3); and *Zur Geschichte deutscher Volkrechte* (edited by Weiss, 2 vols., 1866).

**GHADAMES**, or **Gadames**, a town of Africa, in an oasis near the S. E. corner of the Algerian part of the desert of Sahara, about 300 m. S. W. of Tripoli; pop. about 7,000, mainly Arabs, Moors, and negroes. It contains many gardens, several hot springs, six mosques, and seven schools. Woollen goods are manufactured, and there is a large trade in ivory, wax, hides, ostrich feathers, caoutchouc, &c. The adjacent region abounds with relics of Roman cities, and the town is believed to occupy the site of the ancient Cydamum. It retains considerable importance from being the focus of four commercial roads. The first crosses Fezzan, the second passes through the great desert and leads to Timbuctoo, the third connects with Lake Tchad, and the fourth passes S. of the Atlas chain of mountains, and connects with Morocco.

**GHARA.** See **SUTLER**.

**GHADEIA.** See **GARDAIA**.

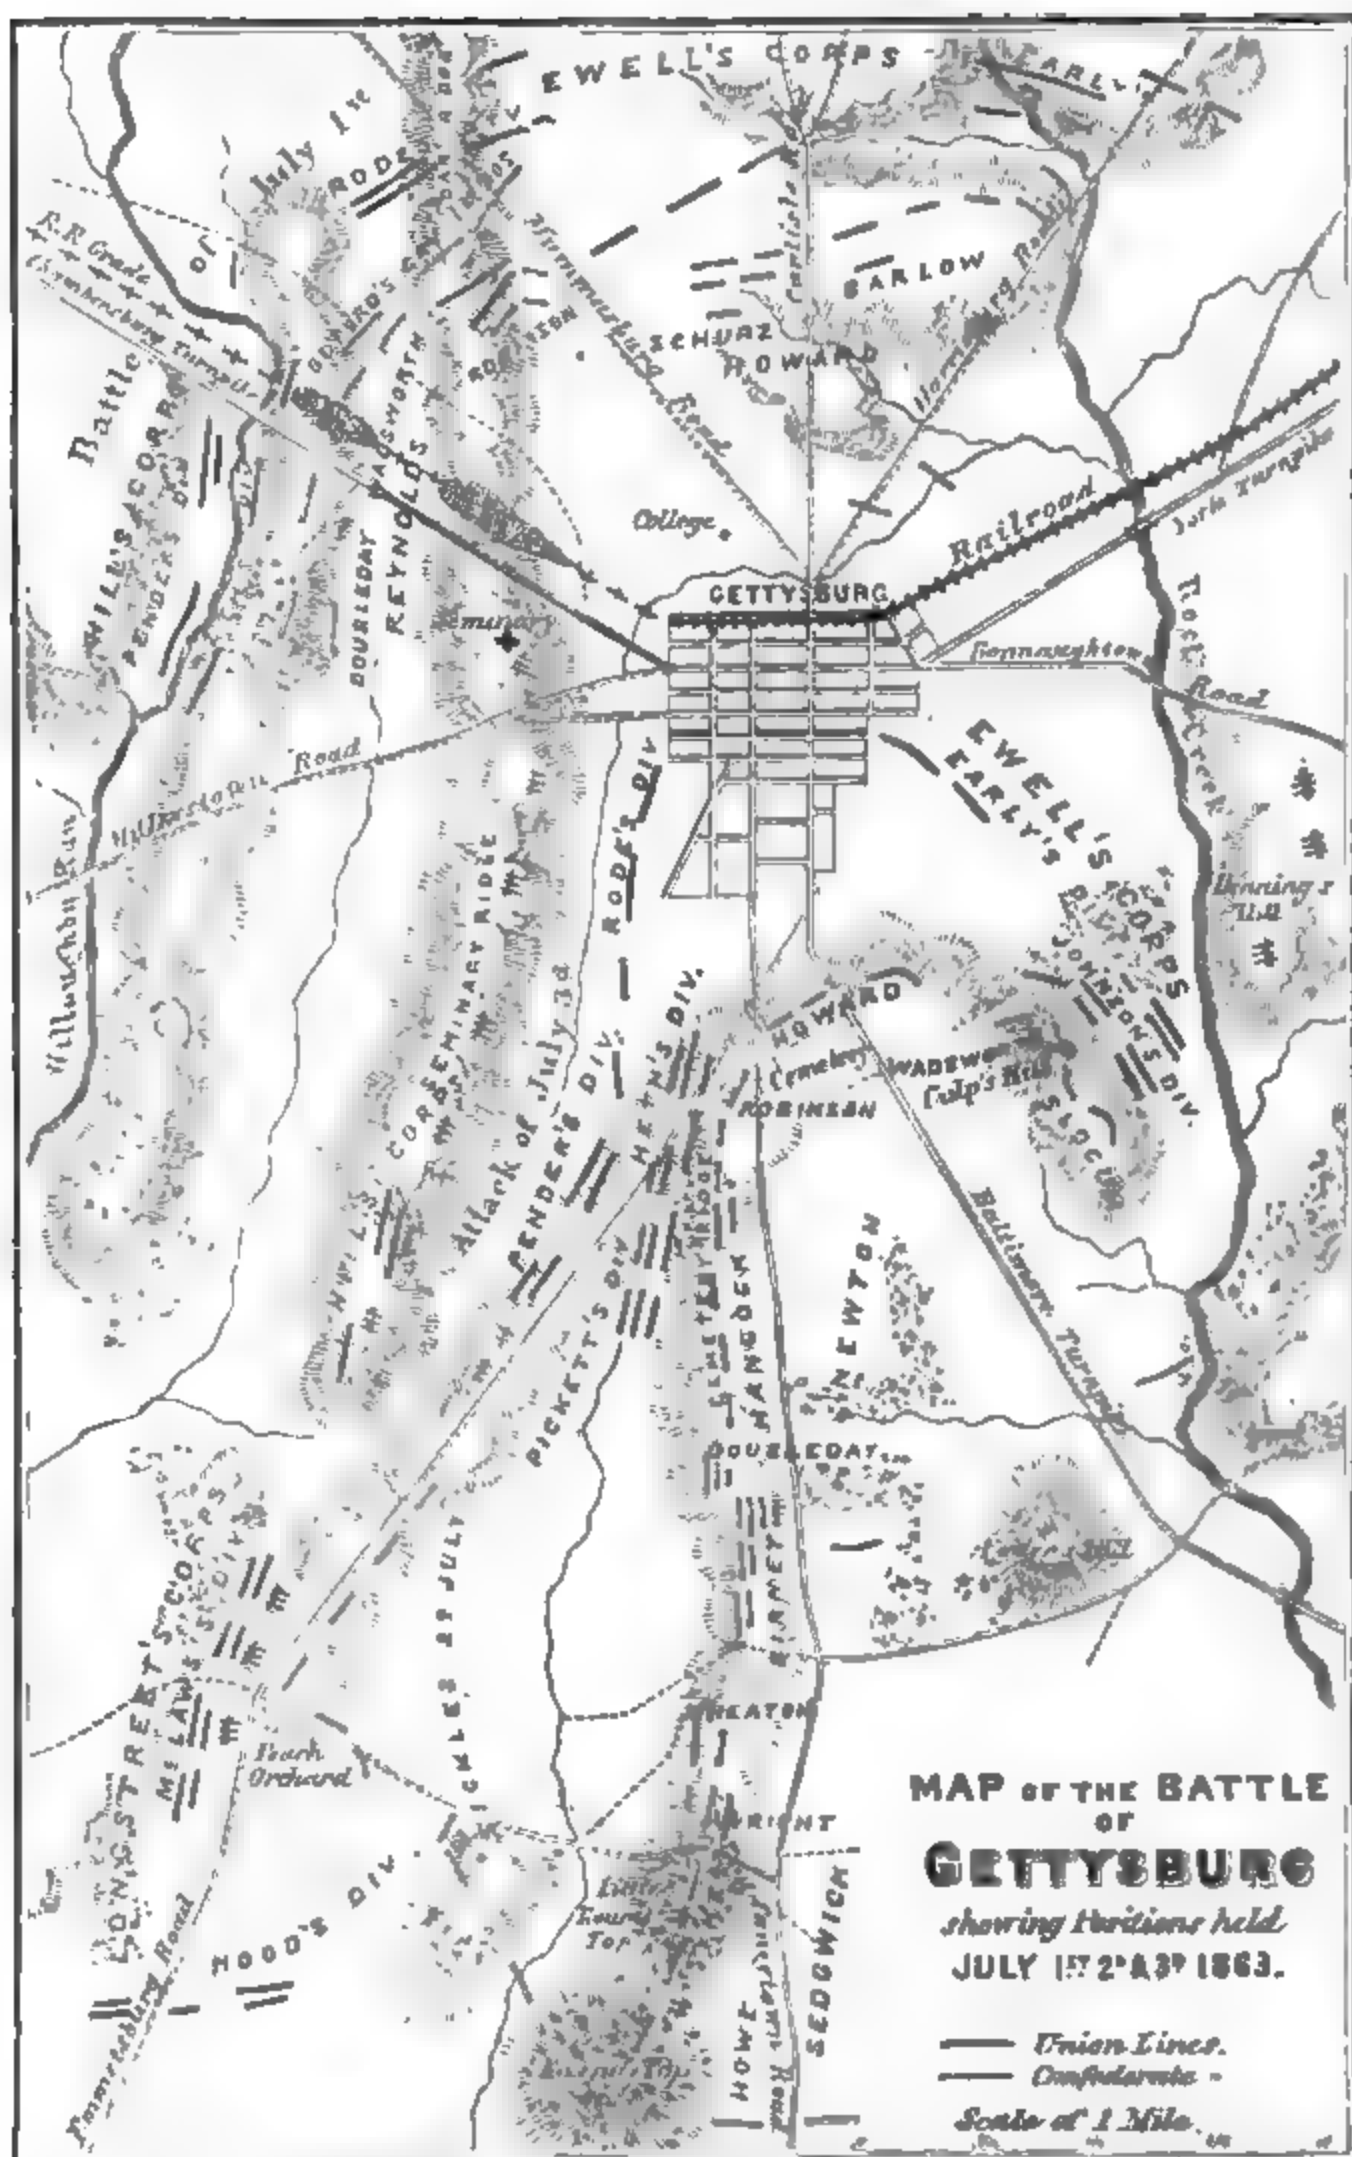

**GHAUTS** (literally, mountain pass; whence, through the Teutonic languages, the English word *gate*), the name of two ranges of mountains in S. Hindostan. The principal of these is the Western, which extends nearly 1,000 m. N. N. W. from near Cape Comorin to the river Taptee, at the mouth of which is Surat. The general direction of the chain is parallel with the coast of the Indian ocean, which it approaches in one place within 6 m.; but it is for the most part at a distance of 20 to 40 m. On its western side it presents a front which

rises boldly from the hilly country between the ranges and the coast; but on the east it gradually slopes away, or spreads in table land, having an average elevation of about 3,000 ft. above the sea, or is continued in long spurs, which stretch out through this central region, known as the Deccan. The country on the west, which embraces the Malabar coast, is comparatively low, its average elevation being roughly estimated at 200 ft. above tide. It is hilly, but also penetrated by creeks and bays making back from the sea; and it is traversed by extensive ravines, which are shaded with forest and jungle. But few gaps break the continuity of the chain, and only one of these is deep enough to drain the waters on the E. slopes into the Indian ocean. This point is in the S. part of the range against the Coimbatore country, from which the river Ponany flows through a break 16 m. wide. Opposite this break it is thought that ships navigating the Indian ocean experience the N. E. monsoons in greater fury than elsewhere. The average height of the Western Ghauts is estimated at 4,000 ft., but some of the peaks rise much higher. Bonasson is said to be 7,000 ft. high, and Dodabetta in the Neilgherries 8,760 ft. The range is not remarkably rough or rocky. A deep rich soil covers the surface, and even upon the summits supports stately forests. The bamboo attains an unusual height; the teak covers the mountain sides; and on the lower hills are forests producing pepper, cassia, frankincense, and other aromatic spices and gums. In the most elevated regions no undergrowth or jungle is encountered, but roads are maintained only at great cost, owing to the violence of the torrents of water during the rainy season; hence the passes across the range are few and difficult. These are occupied by fortresses.—The Neilgherries, among which are some of the most elevated peaks of the range, occupy a tract of some 7,000 sq. m. E. of the main chain N. of Coimbatore. Here the Eastern Ghauts are usually regarded as diverging from the Western; but some trace them further S. through the Carnatic in the range of hills which meet the Western Ghauts a short distance from Cape Comorin. Both this range and the Neilgherries extend across toward the Coromandel coast, meeting near lat. 12° N., and thence the chain of the East Ghauts continues with the coast, some say even to Balasore, which is within 125 m. of Calcutta; but it is commonly regarded as running out before reaching the river Kistnah, the range being thus limited to about 500 m. in length. Its hills are naked and rocky, and seldom attain the altitude of 3,000 ft. The drainage of this region is all toward the bay of Bengal. The S. W. monsoons commence in May and June, with terrific storms of thunder and rain, which vent their greatest fury upon the Western Ghauts. This continues until October, and during this time that part of the Coromandel coast under the lee of the

commanded the Union army, broke up his camp opposite Fredericksburg, and moved northward, on a line parallel with that of Lee, the Blue Ridge being between them. Lee endeavored by an ostentatious stretching out of his force to induce Hooker to pass the mountains and assail him. Finding this unavailing, he moved toward the Potomac, Winchester being the point of concentration of all his corps. Milroy, with 10,000 men, had been lying here, where on June 15 he was assailed by the confederate van, and his force dispersed, losing 2,300 prisoners. Raids were then made into Maryland and Pennsylvania, meeting with so little resistance that an invasion in force of Pennsylvania was resolved upon. On the 24th and 25th the Potomac was crossed at two points, almost within sight of the battle field of Antietam. The two columns, uniting at Hagerstown, Md., pressed on toward Chambersburg, Pa. Hooker on the 28th also crossed the river lower down, and headed toward Frederick City, Md. Lee had by this time gone so far from the river as to leave his communications exposed, and Hooker resolved to fall upon these rather than precipitate a general battle. There were at this time 10,000 Union troops at Harper's Ferry, who could be of no use there. Hooker asked that these should be united with his army. The request was refused by Halleck, who was then general-in-chief, and Hooker thereupon sent in his resignation, which was accepted, and on June 28 Meade was appointed in his place. The confederate corps of Ewell had in the meanwhile reached Carlisle, Pa., and was preparing to advance to Harrisburg, while Longstreet and Hill halted at Chambersburg. The position was now such that Meade by a rapid march could throw his whole force in Lee's rear, isolating him in a hostile country, and cutting off his sources of supply. Lee perceived that the movement northward could be carried no further until he had routed the army which hung menacingly upon his flank and rear; and he resolved to concentrate his whole force in the direction of the enemy, Gettysburg being fixed upon as the place of union. Meade, learning of this movement, resolved to concentrate his columns, which were spread over a wide space, a part under Reynolds being at Gettysburg, and a part under Sedgwick 35 m. southward. The advance was to be drawn back, and the rear brought forward to a point on Pipe creek, 15 m. S. E. of Gettysburg, where Meade resolved to await the attack of the enemy. Lee was wholly ignorant of the position of his enemy; for when he crossed the Potomac, Stuart with the cavalry had been left behind to harass the Union rear, in Virginia, and then to cross the river and rejoin the army at Carlisle. Stuart, crossing at a point below that where Hooker had just crossed, found the enemy between him and Lee, and could reach Carlisle only by making a wide detour; on reaching it, July 1, he found it

evacuated, and the army in movement toward Gettysburg, whither he hastened, but arrived too late to take part in the actions of the first two days.—JULY 1. On the morning of July 1 Hill, whose corps was in the advance, learned that Gettysburg, from which he was distant about 6 m., was occupied by a Union force. Sending back to urge Longstreet to hasten his march, he moved on. In the meanwhile Reynolds had sent out a cavalry reconnoissance in the direction whence Hill was coming, and the forces came in collision about 2 m. N. W. of Gettysburg. Reynolds sent infantry to the support of his cavalry, and the action opened. He was killed at the beginning of the fight, and the command here devolved upon Howard. At first the Union forces were superior, and they gained decided advantages, taking nearly 1,000 prisoners. But in a few hours nearly the whole of Hill's corps came up from Chambersburg, and Ewell's from Carlisle, both numbering about 50,000, while their opponents were less than half as many. The Union force was driven back in confusion through Gettysburg, losing about 5,000 prisoners. The remainder took up a strong position on Culp's hill, just south of the town. The Union loss in this action was about 10,000, half of whom were killed and wounded. The confederate loss in killed and wounded was probably somewhat greater; in prisoners much less. Stuart, who was 15 m. distant, had learned that Lee was fighting at Gettysburg, and sent back with orders to take command of the army there, and to decide what should be done. As it happened, Meade knew nothing of this. Hancock decided that it was the place to give battle, and sent back word to Meade to hurry all his troops to the place. Some of these came up during the night, and early in the following morning, after a march of 35 m., Stuart was with the army in the afternoon. Lee had in the meantime suspended operations until he could bring up his whole army.—JULY 2. Early in the morning the bulk of the two armies were drawn up southward of Gettysburg, at the base of the mile, rises Cemetery ridge. It extends southward, then westward, and finally northward, the whole length of the ridge in shape being like a fish hook, the point of the hook being into several craggy hills, each with a name. That on the extreme end, at the stem of the fish hook, is marked by a ravine from Little Round Top. At the bend of the hook is Cemetery hill forms the barb. The Union army was drawn up along the whole line of Cemetery ridge, opposite this is Seminary ridge, the greater part of Lee's army was drawn up on Seminary ridge, however, lay at the foot of Cemetery ridge, 2 m. distant. The forces present on each hand were about equal, each numbering about 70,000 to 80,000 infantry. The distance between the two ridges is a mile, and the slope of Cemetery

actions of July 2 and 3. It is clear from what followed that Lee greatly underestimated the force opposed to him, and he resolved to attack it in its strong position. Longstreet was to assail the Union left at Round Top, while Ewell was to make on the right, at Culp's hill, "a demonstration, to be converted into a real attack should opportunity offer." Meade had intended that his line should be posted on the ridge directly between Round Top and Cemetery hill. But this ridge, in the centre where Sickles was placed, is comparatively low, sinking down into a valley a few hundred yards wide, beyond which rises another wooded crest running diagonally to the former; and Sickles supposed this to be the one which he was to occupy. Before the error could be corrected the confederate attack had begun, and Meade decided to support Sickles in his present position, although it left an unoccupied space between him and Round Top. As it happened, Hood's division of Longstreet's corps struck this opening. Moreover, by some mischance Little Round Top had been left unoccupied, and this was the key to the entire Union position; for if the enemy could seize this, and place a few guns upon it, the whole line would be enfiladed. The confederates perceived this, and began to swarm up the rugged sides. But just in time Warren, who as engineer was examining the line, discovered the error, and brought up a few regiments. They reached the summit just a moment ahead of the enemy, and forced them back. Again and again until nightfall the assault was unsuccessfully renewed. In the mean time the remainder of Longstreet's corps were pressing fiercely upon Sickles, who was soon borne from the field with his leg shattered. His corps made a stubborn resistance, but was forced back until it reached the crest of the ridge, where a new line was formed. The confederates charged this, but were met with a fire from which they recoiled. Hancock, who now commanded the centre, ordered a counter-charge, by which the enemy were driven back to the ridge previously occupied by Sickles, which they continued to hold. Ewell's demonstration on the Union right was delayed until the action on the left was nearly over; but as most of the Union force had been withdrawn from Culp's hill to aid Sickles, he succeeded in effecting a lodgment within the Union intrenchments. The Union loss in this action was fully 10,000, half of which was in Sickles's corps, which lost nearly half its numbers. This action decided nothing; for the ground which the confederates had won on the Union left was never meant to be held by Meade, and he would gladly have withdrawn from it without a fight; and Ewell's foothold on the Union right was of no importance unless it could be followed up. Still the confederates had gained some apparent advantages; and, says Lee, "These partial successes determined me to continue the assault the next day." From what he could then know, he was justified in this; for he had

every reason to suppose that he had encountered the entire Union force, while less than half of his own had been engaged.—JULY 3. Lee's general plan of attack was similar to that of the preceding day. Ewell was to follow on his advantage, while the main attack was to be made on the centre. But early in the morning Meade had taken the offensive against Ewell, and forced him from the foothold which he had gained. By some unexplained accident Lee was never informed of this mishap, by which a third of his force was left out of action, while Meade was at liberty to concentrate his whole strength upon any point which might be assailed. All the morning was spent in preparation. Seminary ridge formed an admirable position for the confederate artillery, and here directly in front of the Union line they placed 120 guns. A great part of Cemetery ridge is so rugged that artillery could not be placed there; so that although Meade had 200 guns, he could use only 80 at a time. At 1 o'clock the confederates opened fire, which was immediately returned. Many of the Union guns were disabled, but their place was supplied by others. The infantry were so well sheltered behind the crest that they suffered little. After two hours, Hunt, the chief of artillery, gradually suspended fire, "in order to see what the enemy were going to do." Lee, supposing that the Union batteries had been silenced and that the infantry must be demoralized, now ordered the grand attack of the day. This was to be made mainly by Pickett's division of Virginia veterans, who had not yet been engaged. They were to be aided by the brigades of Wilcox and Pettigrew. Exclusive of Wilcox, who did not fairly advance, the attacking column numbered about 18,000. Lee had intended to advance his artillery to support the infantry, but found at the last moment that the ammunition was nearly exhausted, and there was no time to replenish it. The column moved swiftly down the slope of the ridge, and across the plain. All the Union batteries, from Round Top to Cemetery hill, opened upon them, ploughing great furrows through their lines, which were closed up as fast as made. The column at first headed for the left of the Union centre, where Doubleday was posted with 2,500 men, a little in advance of the main line and protected by breastworks of rails and stones. To avoid this the column bent to its left and exposed itself to a severe flank fire. Still it pressed on, until Pettigrew's brigade was within 300 yards of Hancock's line, which had reserved its fire. In five minutes the whole brigade was streaming back in wild disorder. Pickett's division pressed steadily on until it reached Gibbon's front line thinly posted behind a low stone wall. They charged straight over this, among the federal batteries, and for a quarter of an hour there was a struggle with pistols and clubbed muskets. The Union troops hurried from all sides and drove the enemy back down the slope, which was completely

anded by musketry and artillery. To retreat, or stand still was alike impossible. The men flung themselves on the ground, holding up their hands in token of surrender. Of the whole number, not one escaped; the others were dead or prisoners. The attacking column being thus utterly broken in the centre, Meade ordered his right flank to advance and drive back the division of Hood,

which had been held in check upon the ridge won the preceding day. This was done, and many prisoners were captured. Confederate loss this day was about 16,000 killed, wounded, and prisoners; the Union loss was about 3,000. During the night Lee concentrated his force behind the crest of a low ridge, awaiting and probably desiring an attack. In the morning Meade called a council of war, by which it was decided to gain a day and await the development of the enemy's plan." Before night a heavy storm came, under cover of which Lee began his retreat to the Potomac, leaving a strong rear guard to defend the passes through the mountains.

He reached the river, 40 m. distant, on the 19th. The stream, which he had crossed on foot dry-shod a fortnight before, was now swollen by unusually heavy rains and unfordable.

A bridge which he had flung across had been destroyed by a cavalry dash from Harper's Heights, and he had no alternative but to intrench himself and await an attack or the falling of the season. Meade advanced slowly by a much longer route, and on the 12th came in front of Confederate intrenchments. He called a council of war, which, against his opinion, voted to postpone the attack until reconnoissances had been made. On the evening of the 13th an order was issued for an advance the next morning, but when day broke the enemy had disappeared. A slight bridge had been constructed and the river had fallen so as to be fordable at a single point. Ewell's corps crossed by the bridge, and the others by the bridge. The remains of the Confederate army stood safe on the other side, and the invasion of the north, upon which so much had been staked, was at an end.—The loss at Gettysburg, was 23,190, of whom 10,900 were killed, 13,713 wounded, and 6,643 captured. The Confederate loss has never been fully stated; but by the best estimates it was about 36,000, of whom about 5,000 were killed, 23,000 wounded, and 8,000 unwounded prisoners. The entire number of prisoners, killed and unwounded, was about 14,000.—At almost the same moment when the final battle at Gettysburg took place, the negotiations for the surrender of Vicksburg were concluded. These twin disasters mark the epoch of the decline of the confederacy.

**GEYSERS** (Icelandic, *geysa*, to burst forth suddenly), intermittent hot springs found in various parts of the world. In Iceland the principal geysers are in the S. W. part of the island, about 35 m. N. W. of Hecla, and 70 m. from Reykjavik, the chief town. In a circuit

of about two miles are more than 100 springs which send forth hot water, 50 or more in the space of a few acres. These are on the lower slope of a small hill of trappean rock, and above them in the steeper part of the hill under the cliffs of this rock are banks formed by the incrustations of ancient and now nearly extinct geysers. The springs are of different dimensions, and exhibit various degrees of activity; some are uniformly full and quiet, others are constantly boiling, and others only at intervals, with explosive discharges of water and steam. The vapors rising from them form clouds that are seen miles away. They are attended with sulphurous odors; and the geysers of other localities on the island deposit sulphur derived from the decomposition of the iron pyrites in the clays through which the hot waters penetrate. The chief spouting springs of the group are the Great geyser and the Great and Little Strokr. The Great geyser when quiet presents the appearance of a circular mound of silicious incrustations, enclosing a pool, with sides sloping inward at an average angle of  $13^{\circ}$ , and outward at a mean inclination of  $8^{\circ}$ . The height of the mound is about 20 ft. on the lower side, but only half as much on the upper side. The diameter of the basin varies from 50 to 60 ft., and its average depth is 4 ft. In its centre is the mouth of the vertical tube which connects it with the subterranean passages. This tube is about 9 ft. in diameter at its mouth, and 70 ft. in depth. When the geyser is inactive, the basin is filled to the edge with clear water, which has a mean temperature of  $185^{\circ}$  F. and runs gently down the mound, emitting clouds of steam; but for several hours after an eruption the tube is empty to the depth of 4 or 5 ft. At intervals of about an hour and a half a rumbling noise is heard, and the water heaves up in the centre, throwing an increased quantity over the margin. The great eruptions take place at irregular intervals, sometimes exceeding 30 hours. At these times loud explosions are heard beneath the surface, the water is thrown into violent agitation, it boils furiously, and at last is suddenly sent forth in a succession of jets, which increase in force till they become an immense fountain that is lost to view in the clouds of steam in which it is enveloped. The heights reached by these jets have been variously estimated by different travellers. The lowest estimate is 60 or 70 ft.; that of Von Troil in 1772 is 92 ft.; of Sir John Stanley in 1789, 96 ft.; of Lieut. Ohlsen, a Danish officer, in 1804, determined by a quadrant, 212 ft.; of Sir George Mackenzie in 1810, 90 ft.; and of Henderson in 1815, 150 ft. Later visitors, Lord Dufferin, Mme. Ida Pfeiffer, J. Ross Browne, and others, estimate the height at from 60 to 70 ft. The eruptions appear to be diminishing in force and frequency, and it is not improbable that they will cease altogether before the lapse of another century. The discharge continues only about five minutes, when the geyser subsides to a state of tranquil-

Anakim, the Emim, and the Zuzim are described as giants. The sons of Anak were "men of great stature," before whom the children of Israel, as their frightened scouts reported, were "as grasshoppers." Of Og, king of Bashan, and of Goliath, sufficient particulars are given to leave little room for doubt that they were of enormous stature.—The fables of the giants and Titans in classical mythology probably had their origin in terrestrial natural phenomena. The scene of their contests is usually laid in volcanic districts. According to Homer, a race of giants who dwelt in the distant west were destroyed by the gods; Hesiod represented the giants as divine beings, who sprang from the blood of Uranus as it fell on the earth; and by later poets they were described as enemies of Jupiter, who vainly attempted to take Olympus by storm. Scandinavian mythology is peopled with giants (jotuns), who dwelt in forests and caves, amid treasures of gold and silver. They may be a reminiscence of some hostile race of the early times, who had sought refuge in the natural fastnesses of the land. Giants abound in German legends, and may often be traced, like the classical myths, to an origin connected directly with meteorological or terrestrial phenomena. In considering the accounts of giants with which classical literature is filled, it must be borne in mind that all the ancient nations were accustomed to magnify the stature of their kings and heroes. To be thought a giant in strength and in size was the ambition of every warrior. Alexander the Great, in one of his Asian expeditions, caused to be made and left behind him a suit of armor of huge proportions, for the purpose of inducing a belief among the people he had conquered that he was of great stature. Homer exaggerates the size and strength of the heroes of the Trojan war, and declares that the race of man in his day had degenerated in size. More recent writers are not free from similar fictions. King Arthur and his knights and Charlemagne and his paladins were represented to be greater in stature than common men. Roland, the hero of Roncevalles, was said to be of gigantic size; but when Francis I. opened his tomb and tried on his armor it fitted him, although he was no larger than other men of his age. The body of William the Conqueror, examined 400 years after burial, was currently reported to be eight feet in length; but Stowe says that when his tomb in Caen was broken open in 1562, his bones were found to be not remarkable for size. The Germans and Gauls appeared to the Romans to be of immense stature. Cæsar says: "Our shortness of stature, in comparison with the great size of their bodies, is generally a subject of much contempt to the men of Gaul." Tacitus describes the Germans as of robust form and of great stature; and Strabo says that he had seen Britons at Rome who were half a foot taller than the tallest Italians. Yet there is no proof that the men of

these nations were any larger in ancient times than now; on the contrary, the remains found in graves and barrows are usually under the average height of men of the same races of the present day. It is the same with Egyptian mummies. According to Athenæus, a man of four cubits or six feet in height was considered of "gigantic size" in Egypt. Apollodorus gives the height of the "gigantic Hercules" as four cubits; and Phya, the woman who was selected on account of her great height to personate Minerva at Athens in the time of Pisistratus, was only about 5 ft. 10 in. Were it possible to get at the truth concerning the accounts of the giants of antiquity, there is little doubt that half of them would prove to be myths, and the greater part of the remainder gross exaggeration. Pliny's assertion that mankind is gradually decreasing in size rests on no good foundation. On the contrary, a vast amount of evidence can be adduced to show that the men of to-day are equal if not superior in stature to the ancients. The size of the armor, weapons, finger rings, and architecture of antiquity, and the measures of length derived from the human form that have come down to us, all go to prove this. But we do not therefore conclude that all the giants of classical writers are imaginary. The diversity in the height and size of the human family has doubtless existed in all ages, and are not wanting of individuals of great stature. Pliny tells of a man named Gabbara who was over 10 ft. high, of two others, Pasis and Secos, whose skeletons, 9½ ft. in length, were found in the Sallustian garden. According to Appian, the emperor Nero was 7 ft. 6 in. high. In more modern times, the records of men of great stature are not wanting. Merbrock says that he has seen a man 8½ ft. high, with an extraordinary stature. He measured 8 ft. 4 in. in height, and his skeleton, found in London, is 8 ft. 6 in. long. An Irish, born in 1710, was 7 ft. 6 in. high, shoes off; and Patrick J. O'Connell, a Dubliner, is said to have been 7 ft. 6 in. high. Walter Parsons, porter at the London and North Western Railway, England, was 7 ft. 7 in. high. Christian Miller, a German, was 7 ft. 6 in. high in London in 1772. The brothers Knipe were 7 ft. 6 in. high, and M. Louis, a Frenchman, was 7 ft. 6 in. high; the latter had two sons, one of whom, Darden, of Tennessee, was 7 ft. 6 in. high. (DARDEN.) Buffon gives a list of authenticated cases in which men of extraordinary height have been found. In England, a man of 7 ft. 6 in. high, the duke of Wurtemberg, was 7 ft. 6 in. high. In Finland, was 8 ft. 6 in. high. One of the

wick measured  $8\frac{1}{2}$  ft.; Gilli, a giant of Trent, in Tyrol, was 8 ft. 2 in.; and a Swede in the celebrated grenadier guard of Frederick William I. of Prussia stood  $8\frac{1}{2}$  ft.—There is probably not a single well authenticated case, among the many given by ancient writers, of men whose stature has exceeded the natural limits, that has not been equalled in a comparatively modern period. Giants fully 8 ft. high are not unfrequently exhibited. The enormous skeletons, found in times past, of 20, 30, 50, and 100 ft. in length, were without doubt the fossil remains of animals of the primitive world, which only ignorance could have ascribed to a human origin. The progress of comparative anatomy has aided to dispel the errors long prevalent in relation to giants, and there is little fear that men of science of the present age will be deceived, as Buffon was, into representing as human the bones of an elephant.

**GIANTS' CAUSEWAY**, a series of columnar basaltic rocks in the county Antrim, on the N. E. coast of Ireland, between Bengore Head and

Port Rush. For 8 m. along the coast, from Bengore to Fairhead, the land abuts upon the sea in cliffs of basalt, many of which are made up in great part of rude vertical columns which alternate with layers of amorphous beds of the same class of rock. Ranges of these piled upon each other sometimes reach the height of 400 and at Fairhead even 550 ft. As seen from the sea in front, the uniformity of the arrangement of vertical columns and horizontal beds suggests rude resemblances to architectural forms. At the base of the cliffs is a talus of ruins that have fallen from the structures above and slope down to the water. But though the name of Giants' Causeway is often applied to all this coast range, it is properly applicable to but a small portion of it, a locality quite unpretending in its extent or in the grandeur of its features. It is a platform of basalt, composed of closely arranged columns, ranging from 15 to 30 ft. in height. This platform extends from a steep cliff down into the sea, till it is lost below low-water mark. Its

Giants' Causeway.

length exposed at low water is differently given, but probably is less than 600 ft. It is divided across its breadth into three portions, which are called the Little, the Middle, and the Large or Grand Causeway; the first being that on the east. These are separated from each other by dikes of amorphous basalt. The Great Causeway, which is the principal object of interest, is only from 20 to 30 ft. wide, though detached outliers of the same columnar structure standing on the shore near by might be added to increase the width. They no doubt connect with the same group below the surface. The columns are for the most part hexagonal prisms; but they are found also of five, seven, eight, and nine sides, and in one instance

at least of three sides. They are all jointed into short irregular lengths from a few inches to a few feet each, the articulations being perfectly fitted by a convex end entering the concavity of the adjoining piece, so that the blocks form a true column. There is no uniformity in the arrangement of the convexities and concavities, but generally the upper part of this section is concave. The diameter is variable, but ranges generally from 15 to 28 in. The columns fit together with the utmost precision, the corresponding faces of adjacent prisms being always equal, and so continuing from the top of the platform till the lines of separation are lost beneath the ground. It is said that water even cannot penetrate between adjoining

of grave and temperate irony, even on subjects of ecclesiastical solemnity." During the five years of his exile he made the French language more familiar to him than the English. He returned to Protestantism on Christmas, 1754, 18 months after his conversion to Catholicism, and from that time he cared little for theological differences. At Lausanne he formed an attachment for Susanne Curchod, the daughter of a Swiss-pastor; but his father disapproving of the connection, Gibbon philosophically resigned the object of his love, who afterward became the wife of the banker Necker. "I sighed," he says, "as a lover, but obeyed as a son." He returned to England in the summer of 1758, and passed two years chiefly in study at the family seat, Buriton, during which he accomplished a course of classical reading equalled by few of his contemporaries. After residing several months in London, he joined with his father the Hampshire militia, and for more than two years studied practically the military art. Even in the camp he found time for books, and meditated a number of great literary projects. In 1761 he published his *Essai sur l'étude de la littérature*, which he had commenced at Lausanne, designed to defend classical studies against the attacks of the French philosophers. The essay was commended by foreign critics, though scarcely noticed in England. He travelled in 1763, and on his way to Lausanne spent three months in Paris. His essay had given him some renown, and he frequently met D'Alembert, Diderot, Baron d'Holbach, and the other philosophers. After remaining at Lausanne nearly a year, he passed in 1764 into Italy. As he approached Rome he occupied his mind with its antiquities and topography. He read Nardini, Donati, Cluverius; he filled his commonplace books with copious extracts, and stored his memory with abundant learning before he ventured to cross the forum or ascend the Capitoline hill. "It was at Rome," he writes, "on the 15th of October, 1764, as I sat musing amid the ruins of the capitol, while barefooted friars were singing vespers in the temple of Jupiter, that the idea of writing the decline and fall of the city first started to my mind. But my original plan was circumscribed to the decay of the city, rather than of the empire; and though my reading and reflections began to point toward that object, some years elapsed, and several avocations intervened, before I was seriously engaged in the execution of that laborious task." He went south to Naples, returned to Paris, and reached his father's house in June, 1765. At Lausanne in his earlier visits he had formed an intimacy with M. Deyverdun, a young Swiss of fine scholarship, who now visited him yearly at Buriton. With his aid Gibbon began writing a history of the liberty of the Swiss. After two years of study and preparation, the first book, which was written in French, was read as an anonymous production before a literary club of foreigners in London,

by whom it was at once condemned, and the work went no further. He next, in connection with Deyverdun, started the *Mémoires littéraires de la Grande Bretagne*. It was designed to be annual, but two volumes only were printed (1767-'8), when Deyverdun went abroad. His next work was an anonymous and acrimonious attack on that portion of Warburton's "Divine Legation of Moses" in which the 6th book of the *Æneid* is represented as containing an allegorical account of the initiation of *Æneas* in the character of a lawgiver into the Eleusinian mysteries. Though Warburton was the ruling critic of the time, Gibbon's "Critical Observations" (1770) were admitted to have overthrown his hypothesis. The subject was one that could have but little general interest, but the unknown author was mentioned by Heyne of Göttingen as a *doctus et elegantissimus Britannus*. His father having died in November, 1770, Gibbon settled in London, and, with a considerable though somewhat embarrassed estate, lived in studious ease, and began to labor more directly upon his "Decline and Fall," which he had been wont to "contemplate at awful distance." In 1774 he entered the house of commons as member for the borough of Liskeard, and held the seat for eight years a silent supporter of the measures of Lord North. Such was his timidity that he was never able to address the house; more than once he prepared himself to speak, but when the moment for action came his courage wholly deserted him. Near the close of 1775 the first volume of his history was completed. It was refused by the bookseller Elmsley, but accepted by Cadell and Strahan. It appeared in February, 1776; its success was immediate, and, for a quarto and a grave historical production, unprecedented. The first edition was exhausted in a few days; a second and third were soon called for. Hume and Robertson, to whom he sent copies, wrote him congratulatory letters. His splendid theme and imposing style fixed the attention of the public, while his views of Christianity in the last two chapters called forth numerous replies. Watson, Taylor, Milner, Lord Hailes, Davies of Oxford, and Dr. Priestley were the most noted of his assailants; but to Davies alone would the historian consent to reply, because this critic had questioned not his faith, but his historical fidelity. His "Vindication" soon appeared, in which he freed himself from the charge of misquotation. Meantime he studied chemistry and anatomy for recreation. He wrote a political pamphlet in French, in defence of the ministry, and was rewarded with a sinecure place in the board of trade worth £800 a year. He was a member of the Literary club, and a noted conversationist. The second and third volumes of his history were published in 1781, and were received with avidity. On the fall of Lord North's ministry and the loss of his salary by the abolition of the board of trade, Gibbon thought himself too poor to live in England, and went to Lausanne in

1783 to reside with his friend Deyverdun. His fourth volume, embracing the reign of Justinian and the chapter on the Institutes, was already finished, but on the borders of the lake of Geneva he allowed nearly a year to pass before he vigorously resumed his work. He was fond of society, and became highly popular among the Swiss; he gave balls and suppers, frequented assemblies, received many eminent visitors, and even after he was fairly re-seated at his task mingled gayety with constant study. He wrote steadily and rapidly till he completed his work, June 27, 1787. He went to England bearing the manuscript of the last three volumes with him, and on his 51st birthday, the period selected by himself, they were issued. The work was already established in fame; it was translated into German, French, and Italian. His profit from all the volumes is stated to have been £6,000, and that of the booksellers £60,000. The later volumes were reproached for indecencies, veiled for the most part in the learned languages in the notes. Gibbon returned to Lausanne in July, 1788, to find his friend Deyverdun dying. He now wrote his own "Memoirs," which were published posthumously. The French revolution disturbed his repose. Lausanne was filled with French emigrants; the Neckers with their daughter, afterward Mme. de Staël, were his neighbors at Coppet. Lady Sheffield, the wife of his intimate friend Lord Sheffield, died about this time, and Gibbon, partly in the hope of consoling his friend, partly in fear of the revolution, set out for England in the spring of 1793. He had long suffered from hydrocele, which he had studiously concealed, and he died calmly after undergoing three painful operations. He was buried in Lord Sheffield's family burial place at Fletching, in Sussex, and his epitaph was written by Dr. Parr.—In appearance Gibbon was heavy and dull, his countenance showed no trace of intellect, and his features were unattractive. He was fond of fine dress, and his manners were well bred but pompous. He conversed with fluency in sounding language and well ordered periods. His "Decline and Fall of the Roman Empire" is admitted to be the greatest historical work in the English language, and one of the greatest creations of any single intellect. It is hardly less than the history of the world for nearly 13 centuries, for it comprises an account of all the nations who influenced the destinies of the Roman empire both in the West and East. Its vast design, including the decay and ruin of an ancient civilization and the birth and formation of a new order of things; its lucid arrangement, subordinating an infinite variety of subjects to one main and predominant idea, tracing the progress of hostile religions, the influx of successive hosts of barbarians from remote and opposite quarters, the development of the Roman law, the details of ecclesiastical history, and the general rise of modern states, according to the impressions

which they made on the tottering fabric of Roman greatness; its singular condensation of matter, general accuracy, and splendid imposing, and picturesque style, are among the qualities which secure its eminence in historical literature. "Christianity alone," says Milman, "receives no embellishment from the magic of Gibbon's language; his imagination is dead to its moral dignity; it is kept down by a permanent tone of jealous disparagement, or neutralized by a painfully elaborate exposition of its darker and degenerate periods." The best editions are those edited by the Rev. H. H. Milman (3 vols., London, 1838-'9; 2d ed., 1845), which embodies notes by the editor, and by Guizot and others, and that by William Smith (5 vols., 1854-'5), containing many new notes. Dr. Smith's abridgment, "The Student's Gibbon," is valuable as a concise summary of the work. Gibbon's memoirs and miscellaneous writings were published under the care of Lord Sheffield (2 vols., London, 1796, to which a third volume was added in 1815).

**GIBBONS, Grinling**, an English wood carver and sculptor, born about 1650, died in London, Aug. 8, 1721. He was the son of a Dutchman who settled in London; and as he early excelled in his art, Evelyn recommended him to Charles II., who attached him to the board of public works, and employed him in the chapel of Windsor castle, for which he carved the foliage, and in the choir of St. Paul's and the great room at Petworth, the decorations of the latter being regarded as his masterpiece. Among his other carvings are the font in St. James's, Piccadilly, and the base of the equestrian statue of Charles I., in Charing cross. His best known sculpture is the statue of James II. in front of Whitehall. His fame, however, rests mainly on his wood carving, in which his touch was so graceful and delicate that his carved feathers can hardly be distinguished from real ones.

**GIBBONS, Orlando**, an English composer, born in Cambridge in 1583, died in London, Aug. 1, 1625. He was made organist of St. Dunstons' chapel. In 1622 the degree of doctor of music was conferred on him by the university of Oxford. He was principally distinguished by his church music, his anthems, and his madrigals, their day as model compositions. He was also a skilful composer.

**GIBBS, John**, an American theologian, born in Salem, Mass., April 1, 1803. He graduated at Yale college in 1823, and remained at the institution from 1811 to 1815. He was appointed professor of sacred literature in the theological department of Yale college, which he held until his death in 1863. In this department, and in philological studies generally, he was an accurate scholar. His principal works are: a translation of St. Augustine's "Historical Sense of the Scriptures" (New York, 1817); t

Lexicon of the Old Testament" (Andover, 1824); "Manual Hebrew and English Lexicon," abridged from Gesenius (Andover, 1828); "Philological Studies" (New Haven, 1857); and "Latin Analyst" (New Haven, 1858). He contributed also to several important philological works, including the revised edition of Webster's dictionary and W. C. Fowler's work on the English language; and furnished valuable papers to the "American Journal of Science" and other critical periodicals.

**GIBBS, Wolcott**, an American chemist, born in New York, Feb. 21, 1822. He graduated at Columbia college in 1841, and studied chemistry under Prof. Hare at Philadelphia, and medicine at the New York college of physicians and surgeons, taking his degree in 1844. He then went to Europe, and studied under Liebig and Bammelsberg. On his return, in 1849, he was elected professor of chemistry and physics in the New York free academy. In 1863 he became professor in Harvard university, and lecturer on the application of science to the useful arts, which chair he still occupies. He was a member of the United States sanitary commission during the civil war, and was appointed by President Grant scientific commissioner to the Vienna exhibition in 1873. His writings relate exclusively to chemical and physical subjects. He has published about 50 papers, mainly in the "American Journal of Science."

**GIBEON** (Heb., hill city), one of the principal cities of Palestine, about 5 m. N. W. of Jerusalem. Before the conquest of Canaan by Joshua, it was inhabited by Hivites, who by stratagem secured their own safety and protection from Israel; though when the deception was discovered the Gibeonites were degraded to the condition of hereditary "hewers of wood and drawers of water unto all the congregation." It is not mentioned as one of the royal cities of the Canaanites, though described as a great city, and as one of the royal cities. When the five kings of the Amorites besieged Gibeon because of its having made peace with Israel, Joshua marched against them, and at his command, as we are told after the poetical book of Jasher, "the sun stood still, and the moon stayed, until the people had avenged themselves upon their enemies" (Josh. x. 1-14). The Gibeonites were persecuted and nearly exterminated by Saul. On the division of Canaan, Gibeon fell to the tribe of Benjamin; afterward it was given to the Levites; toward the close of David's and in the beginning of Solomon's reign, the sanctuary was there, and there dwelt the high priest. Near to it was a pool, probably the "great waters" referred to by Jeremiah, where Abner was defeated by Joab, and also a great stone, or monumental pillar. It is identified with the modern El-Jib, an irregular village, seated on the summit of a hill, and containing massive ruins.

**GIBRALTAR** (Arab. *Jebel al-Tarik*, mount of Tarik), a fortified rock on the S. coast of An-

dalusia, Spain, belonging to Great Britain, and giving name to a town and bay on its W. side, and to the strait connecting the Atlantic and the Mediterranean. Europa point, its S. extremity, is in lat. 36° 6' N., lon. 5° 21' W. The rock forms a promontory, 3 m. long from N. to S. and about 7 m. in circumference. A low sandy isthmus, 1½ m. long and ¼ m. broad, connects it with the mainland of Spain, having the bay of Gibraltar on the west and the Mediterranean on the east. Two parallel rows of sentry boxes across this flat mark the Spanish and English lines, the space between them being called the "neutral ground." The N., E., and S. sides of the rock are steep and precipitous, and almost inaccessible. On the west it slopes down to the water; here are the town and the principal fortifications. The highest point is about 1,400 ft. above the sea. The rock is composed of gray primary limestone and marble, and was uplifted probably at a recent geologic period, as a marine beach exists more than 450 ft. above the sea. It is perforated by a number of remarkable natural caverns, all of which are difficult of access. The largest, called St. Michael's, has a hall hung with stalactites reaching from roof to floor. Its entrance is 1,000 ft. above the sea, and it is connected with other caverns beneath it of unknown depth. From the sea the surface appears barren; but acacia, fig, and orange trees, and a variety of odoriferous plants, grow in sheltered places. The animal productions are a few kinds of birds, wild rabbits, snakes, and monkeys. The latter, the only wild monkeys in Europe, are of a fawn color and without tails. The climate is temperate and generally healthy, but about once in 12 years an endemic fever, known as the Gibraltar fever, prevails. Immense sums of money and a vast amount of labor have been expended on the fortifications of this stronghold. The most remarkable of the works are the galleries tunnelled in tiers through the solid rock, along the N. front. They are 2 or 3 m. long, and are wide enough to admit a carriage. At every 12 yards they are pierced with ports for guns, so as to command the bay and neutral ground. On the summit of the rock are barracks and fortresses, and strong batteries frown all along the slope on the W. side. More than 1,000 guns are now in position. The garrison consisted in 1872 of 4,308 men. The cost of maintaining the fortress in 1867-'8 was £420,465; estimate for 1872-'3, £219,417.—The town of Gibraltar lies on a shelving ledge on the W. side of the rock, near its N. extremity, 65 m. S. E. of Cadiz; pop. in 1871 (exclusive of the garrison), 16,454, English, Spaniards, Jews, and Moors. It consists chiefly of one spacious street, called the Main or Waterport street, about ¼ m. long and well paved and lighted. The town appears to be more populous than it really is, from the number of strangers visiting it. Great care is taken to prevent the increase of new residents, and

foreigners are allowed to remain only during specified periods, and on giving security for good behavior. The principal buildings are the residences of the governor and lieutenant governor, the admiralty, naval hospital, barracks, and storehouses. There are also Protestant and Roman Catholic churches, four Jewish synagogues, seven regimental and two public schools, a theatre, several hotels, a lunatic asylum, and an almshouse. The garrison library, founded in 1793, contains upward of 20,000 volumes. The water used in the town and by the garrison is collected entirely from the roofs in the rainy season and kept in tanks under the houses. Although a free port, Gibraltar has but little trade. British manufactures for the Barbary states and for other countries bordering on the Mediterranean are distributed through it to some extent. The

chief imports are cotton and woollen goods from England; tobacco, rice, and beer from the United States; sugar and rum from the West Indies; and wines, silks, spices, tea and wax from the East. The chief export is wine. The revenues are usually about £30,000, and the expenditures nearly the same. The entire administration of affairs is in the hands of the military governor.—The bay of Gibraltar, sometimes called Algeciras bay, is formed by the promontory of Gibraltar on the east and the mainland terminating in Point St. Garcia on the west. It is  $4\frac{1}{2}$  m. wide from E. to W., and about 6 m. long from N. to S. Its depth of water, which is 260 ft. at the entrance, gradually diminishes toward the head of the bay, affording good anchorage. The tide rises 4 or 5 ft. Several small streams empty into it on the west and north. Opposite Gibraltar

Gibraltar.

on the W. side, is the Spanish town of Algeciras. On the British side shipping is protected by two long moles.—The strait of Gibraltar, the channel connecting the Atlantic and the Mediterranean, lies between the southernmost part of Spain, from Cape Europa to Cape Trafalgar, and the African coast opposite, from Ceuta point on the east to Cape Spartel on the west. Its length from E. to W. is about 36 m. The narrowest point is N. of Tarifa, where the opposite coasts are but 9 m. apart. From Europa to Ceuta point is about 15 m., and from Trafalgar to Spartel about 25. The greatest depth of water is 960 fathoms. Through the strait a strong central current, from 3 to 6 m. an hour, sets constantly from the Atlantic into the Mediterranean; and two smaller currents, one along each coast, ebb and flow with the tide, running alternately into the Atlantic and the Mediterranean. The excess of water thus

flowing into the Atlantic is supplied by the Mediterranean. Gibraltar, though well known, was not occupied until a comparatively recent period. By the Phoenicians it was called Alube, which the Greeks called Ceuta, the African point. The English name, the Ape's hill, was derived from the fact that these two hills constituted the pillars of Hercules, named, not from the Greek, but from the Tyrian deity, to which the Phoenicians introduced the worship of the strait. The strait is the western boundary of the Mediterranean, and of Gibraltar as a British possession. It was covered by the Moors, and was taken by the leader Tarik (or Tariq) in April, 711. In the year 1462 he built a fortress on the hill, which is now called the Rock.

was erected the castle which is still standing at the N. end of the rock. The fortifications were further strengthened in 1161 under the direction of Alhaug Yaix, a celebrated Moorish engineer. In 1309 the place was captured by the Christians under Guzman the Good, and recaptured by the Moors in 1333. In 1349 siege was laid to it again by Alfonso XI. of Castile, but raised in the following year on account of the plague, which carried off the king. Gibraltar was finally captured by the Christians under the duke of Medina Sidonia in 1462. Under the Spanish crown it was so strengthened as to be considered impregnable; but it was taken Aug. 4, 1704, by a combined English and Dutch fleet under Sir George Rooke and the prince of Hesse-Darmstadt, and held till 1713, when it was confirmed to Great Britain by the treaty of Utrecht. Early in 1727 the Spaniards attacked it with a large force, but raised the siege on the signing of preliminaries of a peace with Great Britain in May of the same year. But the most memorable siege of Gibraltar was that of 1779-'83, sustained against the combined land and naval forces of France and Spain. By June 21, 1779, all communication between the rock and the mainland was cut off, and in July the fortress was completely blockaded. The cannonading began in September on the part of the besieged, but the Spaniards did not open their fire until January, 1780. The attack and defence which followed fixed the attention of Europe for the next three years. On the part of the besiegers all the resources of war were brought to bear both by land and sea. The best engineers of France and Spain directed the approaches; a powerful fleet anchored in the bay, and for three weeks an incessant bombardment was kept up from 80 mortars and 200 pieces of battering cannon. The garrison, commanded by Sir Gilbert Elliott (afterward Lord Heathfield), and numbering 7,000 men, made a heroic resistance. On Nov. 27, 1781, they destroyed the enemies' works in a sortie, but the allies at once reconstructed them, and soon brought 1,000 pieces of artillery to play against the fortress, while 47 ships of the line and innumerable smaller vessels menaced it by sea, and an army of 40,000 men conducted the operations on land. The whole enterprise was directed by the duke de Crillon. Meanwhile Admiral Rodney, having defeated the fleet of Count de Grasse, succeeded in throwing relief into the fort. In September, 1782, the allies attempted to silence the British fire by means of 10 enormous floating batteries constructed by the chevalier d'Arçon in such a manner as to be deemed invulnerable. Each was manned by a picked crew and mounted from 6 to 21 guns. On the 13th they were put in motion, and one of the most dreadful cannonadings known in history was opened on both sides. It continued for several hours with little advantage to either party, but late in the afternoon the effect of the red-hot shot from the

garrison became apparent, and soon after midnight nine of the batteries were on fire. Of their crews about 400 men were saved by the exertions of the British; the rest perished by the flames, explosions, or drowning. The besieged had 16 killed and 68 wounded. Several attempts to storm the rock by land proved equally disastrous. The British received fresh reinforcements, and in February, 1783, the siege was raised on the signing of preliminaries of peace. In 1868 a proposal to surrender Gibraltar to Spain was agitated in England, but did not meet with public favor. As the key to the Mediterranean and one of the chain of fortresses connecting Great Britain with her East Indian possessions, it is of incalculable value for a coaling station, a depot for war material, and a port of refuge.

**GIBSON.** I. A W. county of Tennessee, drained by Forked Deer and Obion rivers; area, 520 sq. m.; pop. in 1870, 25,666, of whom 6,856 were colored. The surface is generally even and the soil fertile. The Mobile and Ohio and the Memphis and Louisville railroads pass through it. The chief productions in 1870 were 116,869 bushels of wheat, 106,775 of Indian corn, 16,319 of peas and beans, 23,440 of Irish and 60,275 of sweet potatoes, 243,746 lbs. of butter, 879 tons of hay, and 9,815 bales of cotton. There were 5,631 horses, 2,955 mules and asses, 5,470 milch cows, 6,883 other cattle, 14,113 sheep, and 53,103 swine; 6 manufactories of agricultural implements, 10 of bricks, 18 of carriages, 5 of furniture, 8 of iron castings, 1 of kindling wood, 7 of saddlery and harness, 1 of sashes, doors, and blinds, 6 wool carding and cloth dressing establishments, 11 flour mills, 1 planing mill, and 15 saw mills. Capital, Trenton. II. A S. W. county of Indiana, bordering on Illinois, area, 449 sq. m.; pop. in 1870, 17,571. It contains coal, and has an undulating surface and a rich soil, watered by the Wabash and Patoka rivers, the former of which forms the W. boundary. The Wabash and Erie canal and the Evansville and Crawfordsville railroad intersect it. The chief productions in 1870 were 457,260 bushels of wheat, 757,933 of Indian corn, 89,807 of oats, 22,979 of potatoes, 102,812 lbs. of butter, 37,440 of wool, 182,031 of tobacco, and 7,564 tons of hay. There were 5,206 horses, 8,795 milch cows, 6,026 other cattle, 15,038 sheep, and 28,222 swine; 11 manufactories of carriages, 1 of furniture, 9 of saddlery and harness, 4 of woollen goods, 3 distilleries, 12 flour mills, and 6 saw mills. Capital, Princeton.

**GIBSON, John**, an English sculptor, born at Conway, North Wales, in 1791, died in Rome, Jan. 27, 1866. His father, who was a market gardener, removed to Liverpool, and young Gibson, after endeavoring to prevail on his parents to allow him to study painting, was apprenticed at the age of 14 to a cabinet maker, and soon after to a wood carver. He attracted the attention of Messrs. Francis, marble cutters, who purchased his indentures and

he had fulfilled his mission, the Israelites solicited him to become their king, but he declined, and held for 40 years the office of judge.

**GIEN**, a town of France, in the department of Loiret, on the right bank of the Loire, crossed here by a fine stone bridge of 12 arches, 38 m. S. E. of Orleans; pop. in 1866, 6,717. It is built on a hill, and has an ancient castle, now used for public offices. The lower part of the town is often overflowed by the rising of the Loire. Pottery, leather, and fine carriages are manufactured, and there is a trade in wine, wool, saffron, coal, &c. Gien is first mentioned at the close of the 8th century as the site of a castle built by Charlemagne. The castle was restored and enlarged in 1494 by Anne of Beaujeu, daughter of Louis XI.

**GISEBRECHT, Friedrich Wilhelm Benjamin von**, a German historian, born in Berlin, March 5, 1814. His father, Karl Heinrich Ludwig, was a dramatist, and his uncle, Heinrich Ludwig Theodor, was a poet and historian. He studied under Ranke, and became a professor at the gymnasium of Berlin, in 1857 at the university of Königsberg, and in 1862 at that of Munich, where he also presides over the historical seminary, and succeeded Sybel as permanent secretary of the historical committee. He wrote the history of the emperor Otho II. for Ranke's *Jahrbücher des deutschen Reichs* (Berlin, 1840); and having discovered and published the *Annales Altahenses*, a long missing manuscript of the 11th century, the Prussian government enabled him to reside from 1843 to 1845 in Italy to collect original materials for his most important work, *Geschichte der deutschen Kaiserzeit* (3 vols., Brunswick, 1863-'5; 3d ed., 1868). In 1874 he undertook a revised edition and continuation of Heeren and Ukert's *Europäischen Staatengeschichte* (72 vols., Gotha, 1823-'74 et seq.).

**GISELER, Johann Karl Ludwig**, a German church historian, born at Petershagen, March 3, 1792, died in Göttingen, July 8, 1854. He interrupted his studies in the university of Halle to serve as a volunteer in the campaign of 1813. In 1815 he resumed his studies, which he combined with teaching. In 1818 appeared his *Historisch-kritischer Versuch über die Entstehung und die frühern Schicksale der schriftlichen Evangelien*, and in 1819 he was appointed professor of theology in the university of Bonn, and in 1831 at Göttingen. His principal work is *Lehrbuch der Kirchengeschichte*. The five volumes published during his lifetime brought the history down only to the peace of Westphalia in 1648; but from the notes and manuscripts which he left, it was continued to the present century by his pupil Redepenning. An English translation of the entire work has been published under the editorial care of Prof. Henry B. Smith (4 vols., New York, 1856-'8). It is especially valuable for the fairness of its citations, the source for each important statement being given at length in notes, which in volume far exceed the text.

**GIESSEN**, a town of Germany, capital of the province of Upper Hesse, in the grand duchy of Hesse-Darmstadt, situated at the confluence of the Wieseck with the Lahn, 30 m. N. of Frankfurt; pop. in 1871, 12,245. It was originally fortified, but its ramparts have been levelled and converted into promenades. The town is well though irregularly built, and contains an old castle, a hospital, arsenal, and two churches. The university, which was founded in 1607, has 58 teachers and about 400 students, a library of 40,000 volumes, an observatory, botanical garden, and museum. Its school of organic chemistry under Liebig has been especially distinguished. Besides the university Giessen has a gymnasium and several other superior schools. Its manufactures consist of hosiery, hats, soap, candles, red and white leather, jewelry, weapons, liqueurs, vinegar, and tobacco. It has also breweries and oil mills, and a considerable trade in cattle.

**GIFFORD, Helen Selma**, countess of, an English poetess, born in 1807, died June 13, 1867. She was a daughter of Richard Brinsley Sheridan, and sister of the duchess of Somerset and of the Hon. Mrs. Norton. She married in 1825 Price Blackwood, a captain in the navy, afterward fourth Baron Dufferin, who died July 21, 1841. In order to be better able to attend her intimate friend, the earl of Gifford, in his illness, she married him in 1862, about ten weeks before his death. She was celebrated for her wit, and in her early days for her beauty, and wrote many songs and ballads, including "The Irish Emigrant's Lament" and "The Farewell of Terence." The present Earl Dufferin, governor general of Canada, is her eldest son.

**GIFFORD, Robert Swain**, an American painter, born in Naushon, Mass., Dec. 23, 1840. He studied in New York with Albert Van Beest, and in 1869 made an extensive sketching tour through California and Oregon, and furnished for Appleton's "Picturesque America" (1872-'3) views of the Columbia river, northern California, and the coast of California. He spent the year 1870 and a part of 1871 in Europe, Egypt, and northern Africa, making sketches. Among his best works are "The Rock of Gibraltar" and "A Lazy Day in Egypt."

**GIFFORD, Sanford Robinson**, an American painter, born in Greenfield, Saratoga co., N. Y., July 10, 1823. His childhood and youth were passed at Hudson, and in 1842 he entered Brown university, where he remained till 1844, when he went to New York and studied drawing, perspective, and anatomy, with a view to figure painting; but in 1845 he determined to devote himself to landscapes. In 1851 he became an associate of the national academy, and in 1854 an academician. In May, 1855, he went to Europe, spent the summer sketching in England and Scotland, passed the following winter in Paris, and in the summer of 1856 made a pedestrian tour through Belgium, Holland, Switzerland, and Italy. The next winter

Anakim, the Emim, and the Zuzim are described as giants. The sons of Anak were "men of great stature," before whom the children of Israel, as their frightened scouts reported, were "as grasshoppers." Of Og, king of Bashan, and of Goliath, sufficient particulars are given to leave little room for doubt that they were of enormous stature.—The fables of the giants and Titans in classical mythology probably had their origin in terrestrial natural phenomena. The scene of their contests is usually laid in volcanic districts. According to Homer, a race of giants who dwelt in the distant west were destroyed by the gods; Hesiod represented the giants as divine beings, who sprang from the blood of Uranus as it fell on the earth; and by later poets they were described as enemies of Jupiter, who vainly attempted to take Olympus by storm. Scandinavian mythology is peopled with giants (jotuns), who dwelt in forests and caves, amid treasures of gold and silver. They may be a reminiscence of some hostile race of the early times, who had sought refuge in the natural fastnesses of the land. Giants abound in German legends, and may often be traced, like the classical myths, to an origin connected directly with meteorological or terrestrial phenomena. In considering the accounts of giants with which classical literature is filled, it must be borne in mind that all the ancient nations were accustomed to magnify the stature of their kings and heroes. To be thought a giant in strength and in size was the ambition of every warrior. Alexander the Great, in one of his Asian expeditions, caused to be made and left behind him a suit of armor of huge proportions, for the purpose of inducing a belief among the people he had conquered that he was of great stature. Homer exaggerates the size and strength of the heroes of the Trojan war, and declares that the race of man in his day had degenerated in size. More recent writers are not free from similar fictions. King Arthur and his knights and Charlemagne and his paladins were represented to be greater in stature than common men. Roland, the hero of Roncesvalles, was said to be of gigantic size; but when Francis I. opened his tomb and tried on his armor it fitted him, although he was no larger than other men of his age. The body of William the Conqueror, examined 400 years after burial, was currently reported to be eight feet in length; but Stowe says that when his tomb in Caen was broken open in 1562, his bones were found to be not remarkable for size. The Germans and Gauls appeared to the Romans to be of immense stature. Cæsar says: "Our shortness of stature, in comparison with the great size of their bodies, is generally a subject of much contempt to the men of Gaul." Tacitus describes the Germans as of robust form and of great stature; and Strabo says that he had seen Britons at Rome who were half a foot taller than the tallest Italians. Yet there is no proof that the men of

these nations were any larger in ancient times than now; on the contrary, the remains found in graves and barrows are usually under the average height of men of the same races of the present day. It is the same with Egyptian mummies. According to Athenæus a man of four cubits or six feet in height was considered of "gigantic size" in Egypt. Apollodorus gives the height of the "gigantic Hercules" as four cubits; and Phya, the woman who was selected on account of her great height to personate Minerva at Athens, in the time of Pisistratus, was only about 5 ft. 10 in. Were it possible to get at the truth concerning the accounts of the giants of antiquity, there is little doubt that half of them would prove to be myths, and the greater part of the remainder gross exaggerations. Pliny's assertion that mankind is gradually decreasing in size rests on no good foundation. On the contrary, a vast amount of evidence can be adduced to show that the men of to-day are equal if not superior in stature to the ancients. The size of the armor, weapons, finger rings, and architecture of antiquity, and the measures of length derived from the human form that have come down to us, all go to prove this. But we must not therefore conclude that all the giants of the classical writers are imaginary. The diversity in the height and size of the human family at present has doubtless existed in all ages. Instances are not wanting of individuals of 8 and 9 ft. in height. Pliny tells of an Arabian named Gabbara who was over 9 ft. high, and of two others, Puer and Phylas, whose skeletons, 9½ ft. in length, were found in the Sallustian garden. In the temple of Capitoline, the statue of Hercules was 10 ft. In more recent times, the records of men of extraordinary size are not wanting. Merbroek says that he saw a man 8½ ft. high, who was of ordinary stature. Ohlshausen measured 8 ft. 4 in.; and his skeleton, now in the Museum of London, is 8 ft. 10 in. long. An Irish, born in 1710, and who took his shoes off; and Francis O'Connell, an Irishman, is said to have been 7 ft. 10 in. high. Walter Parsons, porter to the Duke of Devonshire, England, was 7 ft. 7 in. high. Christian Miller, a native of London, in 1734, was 7 ft. 6 in. high. His brothers Knipe were 6 ft. 10 in. and M. Louis, a Frenchman, was 6 ft. 10 in.; the latter had two sons, one of whom was 6 ft. 10 in. Darden, of Tennessee, was 6 ft. 10 in. DARDEN.) Buffon gives authentic cases in which men have attained an extraordinary height. John Galsworthy, of England, was 7 ft. 5 in. high. Duke of Württemberg was 7 ft. 5 in. high. Finland, was 8 ft., as was also the aut. One of the

wick measured  $8\frac{1}{2}$  ft.; Gilli, a giant of Trent, in Tyrol, was 8 ft. 2 in.; and a Swede in the celebrated grenadier guard of Frederick William I. of Prussia stood  $8\frac{1}{2}$  ft.—There is probably not a single well authenticated case, among the many given by ancient writers, of men whose stature has exceeded the natural limits, that has not been equalled in a comparatively modern period. Giants fully 8 ft. high are not unfrequently exhibited. The enormous skeletons, found in times past, of 20, 30, 50, and 100 ft. in length, were without doubt the fossil remains of animals of the primitive world, which only ignorance could have ascribed to a human origin. The progress of comparative anatomy has aided to dispel the errors long prevalent in relation to giants, and there is little fear that men of science of the present age will be deceived, as Buffon was, into representing as human the bones of an elephant.

**GIANTS' CAUSEWAY**, a series of columnar basaltic rocks in the county Antrim, on the N. E. coast of Ireland, between Bengore Head and

Port Rush. For 8 m. along the coast, from Bengore to Fairhead, the land abuts upon the sea in cliffs of basalt, many of which are made up in great part of rude vertical columns which alternate with layers of amorphous beds of the same class of rock. Ranges of these piled upon each other sometimes reach the height of 400 and at Fairhead even 550 ft. As seen from the sea in front, the uniformity of the arrangement of vertical columns and horizontal beds suggests rude resemblances to architectural forms. At the base of the cliffs is a talus of ruins that have fallen from the structures above and slope down to the water. But though the name of Giants' Causeway is often applied to all this coast range, it is properly applicable to but a small portion of it, a locality quite unpretending in its extent or in the grandeur of its features. It is a platform of basalt, composed of closely arranged columns, ranging from 15 to 30 ft. in height. This platform extends from a steep cliff down into the sea, till it is lost below low-water mark. Its

Giants' Causeway.

length exposed at low water is differently given, but probably is less than 600 ft. It is divided across its breadth into three portions, which are called the Little, the Middle, and the Large or Grand Causeway; the first being that on the east. These are separated from each other by dikes of amorphous basalt. The Great Causeway, which is the principal object of interest, is only from 20 to 30 ft. wide, though detached outliers of the same columnar structure standing on the shore near by might be added to increase the width. They no doubt connect with the same group below the surface. The columns are for the most part hexagonal prisms; but they are found also of five, seven, eight, and nine sides, and in one instance

at least of three sides. They are all jointed into short irregular lengths from a few inches to a few feet each, the articulations being perfectly fitted by a convex end entering the concavity of the adjoining piece, so that the blocks form a true column. There is no uniformity in the arrangement of the convexities and concavities, but generally the upper part of this section is concave. The diameter is variable, but ranges generally from 15 to 28 in. The columns fit together with the utmost precision, the corresponding faces of adjacent prisms being always equal, and so continuing from the top of the platform till the lines of separation are lost beneath the ground. It is said that water even cannot penetrate between adjoin-

in America," "First Snow," "Winter in Vermont," and "Bernese Alps by Sunrise." Since 1870 he has lived in France.

**GIGOUX, Jean François**, a French painter, born in Besançon in 1806. He is said to have been originally a blacksmith, and became famous in 1835 by his "Death of Leonardo da Vinci." In 1850 he exhibited "The Dead Christ" and "The Death of Cleopatra," and in 1852 "Galatea," which he has also engraved. One of his largest works, executed for the council of state and representing "Charlemagne dictating his Capitularies," was burned in 1871.

**GIJON**, a seaport of Asturias, Spain, on the bay of Biscay, in the province and 15 m. N. N. E. of the city of Oviedo; pop. about 10,500. It is built on a low headland, surmounted by a hill. Some ancient walls surround the upper or old town, and a fortress and batteries guard the new town, which reaches down to the shore. The former Augustinian convent is used as a cigar manufactory, employing 1,400 persons. There are active fisheries, and some coasting trade. The harbor is safe, though not easily accessible. The first quay was built here under Charles V. in 1552-'4, and a new one was constructed in 1768. The Spanish armada was repaired here in 1588. In 1810 the town was sacked and its shipping destroyed by the French, under Bonnet.

**GILA**, a river of New Mexico and Arizona, the principal tributary of the Colorado river of the West. It rises in the Sierra Madre mountains in Socorro co., New Mexico, flows S. W. to near the Arizona boundary, where it bends S. and then pursues a general W. course through that territory to its junction with the Colorado, about 180 m. above its mouth. Its sources are about 5,000 ft. above the sea. The principal tributaries from the north are the Rio Nutroso, Prieto, Bonito, San Carlos, Salt river or Rio Salado, and Agua Fria creek; from the south the Rio San Domingo and San Pedro. The Santa Cruz river, after a course of nearly 100 m., is lost in the sands of the desert, and seldom discharges its waters into the Gila. For more than half its entire length, which is nearly 500 m., the Gila passes through mountains, and in some places is unapproachable, being buried between walls of perpendicular rock nearly 1,000 ft. high. It emerges from the mountains in lon. 111° 25' W., after which its course is through an open and comparatively level country to its termination. In the last 300 m. it has an average fall of 5 ft. per mile, and averages 60 ft. in width, 3 ft. in depth, and in velocity 2 m. an hour. In the lower portion the valley is from 1 to 3 m. wide; about 150 m. from its mouth there is a considerable bend to the north, where the valley for 25 m. is from 5 to 10 m. wide. The valley is in many places covered with mezquite and cottonwood, and on its margin with the willow. Several varieties of cactus, including the pitahaya (*cereus giganteus*), grow on the table land near the river, but never in the alluvial lands in its valley.

The ruined edifices, broken pottery, and traces of irrigating canals found along this river, show that its former population was much larger than at present. One of these structures is three stories high and in good preservation. The others are in a ruined state, and present little more than dilapidated walls, tumuli, mounds, &c., of crumbling adobe, of which the buildings were constructed. (See *CASA GRANDES*.) About 200 m. from the Colorado, in one of the finest portions of the valley, is the reservation of the Maricopa and Pima Indians. It is intersected in all directions by irrigating canals, and produces abundant crops. Further E., among the mountains, are many luxuriant valleys where once existed a considerable population, as is evident from the traces of cultivation and the ruins which remain.

**GILBERT, Sir Humphrey**, an English navigator, half brother of Sir Walter Raleigh, born at Dartmouth in 1589, lost at sea about the end of 1583. He was educated at Eton and Oxford, followed the military profession, and was knighted in 1570 for his services in Ireland. Being interested in geographical discovery, both from love of fame and of adventure, he sailed in 1583 with five vessels and 260 men, prepared to take possession of the northern parts of America, and founded a colony in Newfoundland, which, however, did not prove permanent. On the return his vessel, of only 10 tons burden, foundered, and all perished. He published a book in 1576, "A Discourse of a Discovery for a new Passage to Cathay," to prove the possibility of a N. W. passage.

**GILBERT, Sir John**, an English painter, born in 1817. He exhibited in 1836 a water-color drawing, "The Arrest of Lord Hastings," in the Suffolk street gallery, and an oil painting in the royal academy. In 1839 he first exhibited in the British institution, where he has been represented almost every year since. He has made many illustrations for books and pictorial newspapers, especially for the British classics, concluding with an edition of Shakespeare, and for the "Illustrated London News." In 1852 he was elected an associate, in 1853 a member, and in 1871 (when he was knighted) president of the society of painters in water colors. He is an associate of the royal academy, and honorary president of the Liverpool society of water-color painters. His best known oil paintings are "Don Quixote giving advice to Sancho Panza," and other subjects from Cervantes; "The Education of Gil Blas;" "A Scene from Tristram Shandy;" "Othello before the Senate;" "The Murder of Thomas à Becket;" "The Plays of Shakespeare," a tableau introducing the principal characters in each play; "Charge of Cavaliers at Naseby;" "A Drawing-room at St. James's;" "A Regiment of Royalist Cavalry;" "Rubens and Teniers;" "The Studio of Rembrandt;" "Wesley and Buckingham;" "A Convocation of Clergy;" and "The Entry of Joan of Arc into Orleans."

**GILBERTINES**, an English religious order, so called from the founder, St. Gilbert of Sempringham (born in 1083, died Feb. 4, 1189). They were also called the "Order of Sempringham." Gilbert, who was by birth lord of Sempringham and Tirington, had become as a priest pastor of both places. He first built a convent near the church of St. Andrew for seven poor maidens, which became so flourishing that he was called upon to establish several others in various parts of the kingdom. Having in vain endeavored to unite these houses to the order of Cîteaux, Gilbert built a monastery of canons regular near each convent, gave to the canons the rule of St. Augustine, to the nuns that of St. Benedict, and placed the lay brethren who served them under the rule of Cîteaux. This order with its constitutions was approved by Eugenius III., and confirmed by his successors. It numbered at the founder's death 13 double convents, besides hospitals for the sick and asylums for widows, orphans, and the poor, with 800 monks and upward of 1,200 nuns. The Gilbertines were confined to England. Sempringham afforded an asylum to Thomas à Becket during his quarrel with Henry II. At the suppression of monasteries under Henry VIII. the order possessed 21 houses and 11 double convents. The Gilbertine rule is given in full by Holstenius. See also Hurter, *Geschichte des Papstes Innocenz III. und seiner Zeitgenossen*.

**GILBERT ISLANDS**, or **Kingsmill Group**, a cluster of coral islands in the Pacific, on both sides of the equator, between lon. 172° and 174° 30' E.; pop. estimated at 60,000. The largest are Taputeonea or Drummond, and Tarawa or Cook islands, the former 30 m. long by about  $\frac{1}{2}$  or  $\frac{3}{4}$  m. wide, and the latter 20 m. long. Almost the only cultivated products are the cocoanut and pandanus, which form the staples of food, and a species of taro (*arum cordifolium*), highly prized by the natives. The breadfruit is found on the northern, though not on the southern islands. The climate is equable, and though warm is not very oppressive. The inhabitants resemble the Malays. The people are divided into three classes, chiefs, landholders, and slaves. There is no general authority recognized throughout the group, but there are several kings, one of whom rules over three of the islands, while others are scarcely respected in any. In some places the government is administered by public assemblies. The islanders are fond of war and prone to suicide, but they are kind to their children, generous, hospitable, and more considerate of women than is usual among savages. They are said to eat human flesh occasionally, but are not habitual cannibals. Their clothing is made of the leaves of the pandanus; their houses and canoes, though constructed of rude materials, are superior in size, strength, and elegance to any others in the Pacific. The islands have several good harbors, but are seldom visited by vessels.

**GILBOA**, a mountain in Palestine, between the river Jordan and the plain of Esdraelon, the scene of the defeat and death of Saul and Jonathan. The name Gilboa signifies a bubbling fountain, and was probably taken from a large fountain at the northern base, called in Scripture the well of Harod, or the fountain of Jezreel. The ancient name is preserved in the village on the mountain, called now Jelbun, and in the time of Jerome Gelbus. The fountain is now known as Ain Jalud. The mountain rises not more than 600 ft. above the plain, but extends E. and W. about 10 m. Its sides are white and barren. Near the fountain of Jezreel was the ancient city of that name, and at this place the Israelites encamped before the battle; while the Philistines pitched at Shunem (now Solam), 8 or 10 m. north, upon the opposite rising ground. The battle was fought, according to the common chronology, in the year 1055 B. C.

**GILDAS**, surnamed "the Wise," a British historian, born, according to some authorities, in 493, according to others in 511, died in 570 or 590. He was the son of Caw, a British prince who emigrated to Wales to avoid subjection to the Anglo-Saxons, and the Welsh bard Aneurin is supposed to have been the same person or his brother. (See ANEURIN.) His only complete work extant is a short Latin composition on British history, entitled *De Calamitate, Excidio et Conquestu Britannia*, in which he mourns over the ruin of his country, and inveighs against the British kings and clergy. It was first published by Polydoro Vergil in 1525, and has been often reprinted. The best edition is by Stevenson, under the care of the English historical society (London, 1838). Translations have been published by Habington (1638), and by Dr. Giles in "Bohn's Antiquarian Library" (1848). It is said by Wright that there is no independent authority for the existence of Gildas, or for the historical truth of the work attributed to him, which he regards as a forgery of the 7th century.

**GILDEMEISTER, Otto**, a German writer, born in Bremen, March 13, 1823. He studied at the university of Bonn, and became in 1845 connected with and in 1850 editor-in-chief of the *Weserzeitung*. In 1852 he was chosen secretary of the Bremen senate, in 1857 senator, in 1866 representative in the diet of the North German confederation, and in October, 1871, burgomaster. He has translated into German the complete works of Byron (6 vols., Berlin, 1864), and many plays of Shakespeare for Bodenstedt's complete edition; and his version of Shakespeare's sonnets was published in 1871.

**GILDING**, the covering of the surfaces of bodies with a thin coating of gold. This method of economizing the precious metal, and imparting to solid bodies the appearance of being wholly composed of it, was practised at very remote periods. The sacred books allude to it; in Exod. xxvi. 29 there is a com-

mand to overlay boards and bars with gold. That the early Egyptians understood it well is evident from the gilding of the coffins of Theban mummies, in which the gold leaves resemble those now prepared. Homer makes mention of it, and the later Greeks thus decorated the exterior sculpture of their temples and statues. The Romans after the destruction of Carthage applied the process to ornamenting the ceilings of their public buildings, and at last of their private houses also. The thickness of the leaf is spoken of by Martial as like a vapor, and by Lucretius the substance is compared to a spider's web. According to Pliny, an ounce of gold was made into 750 leaves, each four fingers square. This is about three times the thickness of the leaf now in common use; but some qualities are so thin that 290,000 sheets make a pile only one inch in height; and specimens have been made only  $\frac{1}{357,500}$  of an inch thick, which is 1,200 times thinner than ordinary printing paper. In modern times the use of gilding in architecture has been carried to the greatest extent by the nations of Further India. It is practised by them with great skill and in the most profuse manner.—Besides the method of gilding by covering objects with gold leaf, there are processes of modern invention, distinguished as chemical gilding, in which the gold is incorporated with the substance of the article it covers, and the same quantity is thus made not merely to spread over a much larger surface, but to be permanently attached to metallic bodies, so as to withstand the action of heat and of atmospheric agents without injury; an art incompatible with the attainments of the ancients in chemistry.—Gilding with gold leaf is distinguished as the mechanical branch of the art; and of this there are two distinct processes, one of which is called burnish gilding or gilding in distemper, and the other oil gilding. In the former the article to be ornamented, as the moulding of a picture frame, is received from the joiner before it is made up. A priming of hot size and whiting is first applied, and when dry all irregularities in the moulding are corrected with the same composition, made of the consistency of putty, which then receives four or five coats of the priming. This, which is now  $\frac{1}{4}$  to  $\frac{1}{2}$  of an inch thick, is carefully trimmed around the edges and smoothed with pumice stone and glass paper. This is the foundation for the so-called gold size (the bed upon which the gold leaf is to be laid), a composition of clay, red chalk, plumbago, suet, and bullock's blood; or, as used by the French, of a pound of Armenian bole to two ounces of red hematite and as much galena, each ground by itself in water, then mixed and ground with a spoonful of olive oil, and at last tempered with a clear white glue carefully prepared from sheep skins. When used, it is first melted with thin size, and while warm is laid on with a brush. The leaf is then laid on by means of a brush

called a tip, an operation which requires considerable dexterity. When the whole is covered and dried, the work, or any portion of it, is burnished with smooth agates or flints as handles for this use.—Oil gilding is practised by several different methods. For large objects especially those exposed to the weather and of metallic composition, the priming used is Paris white lead mixed with linseed oil and a little oil of turpentine. For equipages and indoor work a varnish polish is much used over the gold. For elaborately designed frames of gilding and burnish gilding are often employed upon the same piece, care being taken that the applications for the former do not touch the spots intended to be burnished, which are treated in the manner already described. The frames intended for this process are furnished to the gilder made up. They are then thoroughly washed, and afterward receive two or three coatings of thin white, and more upon the parts to be burnished. A strong size called clear cole is then laid in several coats over those parts only intended for oil gilding, and upon this the oil gold size, a mixture of boiled linseed oil and ochre. By standing over this becomes ready for the gilding, effected without using water. The pressed with cotton wool into all the portions, and when all is laid the work is covered over with a brush, by which its irregularities are removed, and the gold is distributed.—Book covers are ornamented with gilt letters and figures in the following manner. If of cloth, the leaf is laid on over the parts to be ornamented, and the cover is pressed in a press, in which a heated plate having the intended designs cut in it is powerfully pressed against the cloth. The heat of the plate melts the glue on the back side of the cloth, and thus fastens the gold to the fabric. Leather covers receive a coating of gelatine or of the white glue dissolved in water, upon which when dry a thin layer of acceptable application of oil is laid, and the gold leaf is then laid on in the case of the cloth. The letters and figures are gilded in the bookbinder's shop by means of a gelatine solution and a brush, which the gold leaf is laid on and burnished. Chemical gilding is applicable to metallic surfaces, as of wood, leather, or iron, and with some preparation by which they are rendered fit for it.—Wash gilding is another branch of this art in which the surface is first cleaned and burnished by means of an amalgam. In other processes it is effected by the action of copper, or an amalgam of copper, zinc, or zinc and copper, which is suited for the amalgam. The color is then laid on the surface to be gilded, which is then cleaned and burnished, and it is then

solution made of 100 parts by weight of mercury in 110 of nitric acid, of specific gravity 1.33, diluted with 25 times the weight of the whole of pure water. This application leaves a coating of mercury upon the metal, which is more ready to take the amalgam than is the metal itself. Both the mercurial solution and amalgam are sometimes applied together by means of the gilder's scratch brush, which is dipped into the former and immediately rubbed over the latter, and then applied to the metal; the process being repeated as often as necessary. After the application the article is washed in water and exposed to glowing charcoal to expel the mercury. The amalgam is prepared by heating small particles of gold to redness and throwing them into a quantity of mercury heated so as to emit fumes, and stirring with an iron rod till the gold is dissolved. There should be about eight times as much mercury as gold, the excess of the former being removed by squeezing the amalgam through buckskin. The composition then contains about 67 parts of mercury to 33 of gold. The gold thus deposited is of a dull yellow, and still retains some mercury, which is removed after washing and scrubbing the article with a scratch brush acidulated with vinegar, by applying gilding wax, and again heating. The wax is a mixture of beeswax with some of the following substances, viz.: red ochre, verdigris, copper scales, alum, vitriol, borax. When the wax is burned off, the color of the gilding is found to be improved, and it is still further heightened by burnishing. The amalgamation process is not well adapted for gilding articles of iron and steel, an oxide of iron being produced by the acid applications, which prevents the adhesion of the amalgam. For these the best method is to cover them with gold leaf. Copper may be treated in the same way. The metal is heated till it begins to assume a blue color; a sheet of gold leaf is then laid on and gently pressed with a burnisher, and the article is again heated. Other sheets are laid over the first to the desired thickness and heated, and the last is burnished down cold. The surface of iron, whether wrought or cast, or of steel, is sometimes covered with a coat of copper.—To gild silver, a very good process is that called cold gilding. Sixty grains of fine gold and 12 of rose copper are dissolved in two ounces of aqua regia. The whole of the solution is absorbed by linen rags, which are then dried and burned to ashes. The black powder thus obtained is applied upon the silver, which has been annealed and polished, and is rubbed with a piece of moistened cork or washed leather. Burnishing completes the process.—A method of gilding buttons and other articles by immersing them in solutions of gold was introduced into the establishment of the Messrs. Elkington, in Birmingham, in 1836, by which the injurious effects of the amalgamating process on the health of the workmen were avoided. To a solution of chloride of gold prepared from one part of gold,

30 parts of bicarbonate of potassa are gradually added, and then 30 parts more of bicarbonate dissolved in 200 parts of water. The whole is then boiled two hours, and the color of the liquid changes from yellow to green. The articles, being perfectly well cleaned and annealed, are immersed for an instant in a mixture of equal parts of nitric and sulphuric acids, to which, if the gold is intended to have a dead appearance, a little chloride of sodium is added. The articles, washed in water, are plunged in the gold solution, and left half a minute, when they are removed, again washed, and dried in hot sawdust. Articles of German silver, of platinum, or of silver, may be gilded by suspending them by copper or zinc wires for a time in the liquid.—For gilding porcelain or glass, gold precipitated by sulphate of iron is mixed with  $\frac{1}{12}$  its weight of oxide of bismuth and a small quantity of borax and gum water, and the mixture is then applied with a camel's hair pencil. The article is heated in a muffle, and when taken out the gold is burnished, and finally cleansed with vinegar or white lead. Vases and articles not exposed to wear may be gilded by fixing gold leaf upon them with copal varnish. Silks or other woven fabrics may be gilded by immersing them in a neutral solution of terchloride of gold, or moistening them with it in design, and then exposing them to the action of hydrogen, which reduces the gold to a metallic state.

**GILEAD**, the name of a mountain group in the eastern division of ancient Palestine. From it the southern districts of the same division were also called Gilead, which is often mentioned in contradistinction to Bashan in the north, but exceptionally also as including the latter region. This was rich in pastures, and renowned for its aromatic simples, from which balsam was prepared. Among its rivers were the Jabbok and the Arnon.

**GILES**. I. A S. W. county of Virginia, intersected by Kanawha or New river; area, 350 sq. m.; pop. in 1870, 5,875, of whom 598 were colored. The surface is high and rugged, the mean elevation being 1,600 ft. above the sea; the principal summits are Peter's and Walker's mountains. The soil of the uplands is poor, but the valleys and river bottoms are very fertile. The chief productions in 1870 were 53,598 bushels of wheat, 12,633 of rye, 105,402 of Indian corn, 23,474 of oats, and 1,351 tons of hay. There were 1,295 horses, 1,346 milch cows, 2,095 other cattle, 4,471 sheep, and 5,247 swine. Capital, Pearisburg. II. A S. county of Tennessee, bordering on Alabama, watered by Elk river and some of its branches; area, 600 sq. m.; pop. in 1870, 32,413, of whom 12,738 were colored. It has a slightly uneven surface and a fertile soil. The chief productions in 1870 were 145,635 bushels of wheat, 2,054,163 of Indian corn, 70,512 of oats, 32,556 of Irish and 28,074 of sweet potatoes, 228,560 lbs. of butter, 1,644 tons of hay, and 8,367 bales of cotton. There

were 7,672 horses, 3,458 mules and asses, 6,536 milch cows, 9,886 other cattle, 18,658 sheep, and 47,700 swine; 2 manufactories of cotton goods, 7 of saddlery and harness, 1 of tin, copper, and sheet-iron ware, 2 flour mills, 11 saw mills, 6 tanneries, and 5 currying establishments. Capital, Pulaski.

**GILES, Henry**, an American clergyman and lecturer, born in county Wexford, Ireland, Nov. 1, 1809. He was educated in the Roman Catholic church, but after various changes of opinion joined the Unitarians, and officiated as pastor in Greenock for two years, and in Liverpool for three years. In 1840 he came to America, where he has been extensively engaged in lecturing, with occasional services in different parishes as a preacher. He has published "Lectures and Essays" (2 vols., Boston, 1845), "Christian Thoughts on Life" (1850), and "Illustrations of Genius in some of its applications to Society and Culture" (1854). He has also written much for periodicals, has addressed literary societies and library associations, and given a course of lectures before the Lowell institute in Boston on the "Genius and Writings of Shakespeare." He now (1874) resides in Quincy, Mass.

**GILES, William Branch**, an American statesman, born in Amelia co., Va., Aug. 12, 1762, died at "The Wigwam," in the same county, Dec. 4, 1830. He entered Princeton college, N. J., but left it before completing the usual course. He studied law with Chancellor Wythe, was admitted to the bar, and practised for five or six years. In 1790 he was elected by the federal party in the Petersburg district to fill a vacancy in congress, and was several times reelected. His opposition to the bill creating a bank of the United States led to his estrangement from the federal party, and to his affiliation with the democrats. On Jan. 23, 1793, he made in the house an attack upon Alexander Hamilton, then secretary of the treasury, charging him with corruption and peculation. Hamilton vindicated himself triumphantly in a report, and Giles replied by proposing resolutions censuring the secretary for undue assumption of power, and for want of respect for the house. These resolutions were laid on the table by very large majorities. In 1796 Giles strongly opposed the creation of a navy and the ratification of Jay's treaty with Great Britain, and in 1798 the proposed war with France for her outrages on American commerce. In the latter year he became a member of the legislature of Virginia, where he cooperated with Madison in procuring the passage of the celebrated resolutions of '98. In 1801 he was again elected to congress. In 1804 he was chosen United States senator, and took at once the position of democratic leader in the senate, and held it till 1811, when he openly manifested his opposition to the administration of President Madison. He abandoned public life in 1815, and remained in retirement till 1826, when he was induced

to become a member of the legislature of Virginia, principally from his strong opposition to the project of calling a convention to revise the constitution of the state. In the same year he was elected governor, and held the office for three years. The bill for calling a convention was revived and passed at the session of 1827-'8, and Mr. Giles while governor was chosen a member of it. The convention met in 1829-'30, and he took a distinguished part in its deliberations. He published in 1811 "Political Letters to the People of Virginia," and subsequently various letters.

**GILFILLAN, George**, a Scottish author, born at Comrie, Perthshire, in 1813. The son of a minister of the Secession church, he was educated for the same profession, and has officiated since 1836 as minister of the School ward congregation in Dundee. His first literary sketches appeared about 1842 in the "Dundee Herald," and were collected in 1845 under the title of "A Gallery of Literary Portraits;" a second series appeared in 1849, and a third series in 1855. He has also published "Bards of the Bible" (1850); "The Book of British Poesy, Ancient and Modern" (1851); "The Martyrs, Heroes, and Bards of the Scottish Covenant" (1852); "The Grand Discovery" (1854); "History of a Man" (1856); "Christianity and our Era" (1857); "Alpha and Omega," a collection of sermons (1864); and "Night," a poem (1867). He has contributed much to periodicals, and has edited a collection of "British Poets," in 48 vols., with biographical sketches and critical notes.

**GILLESPIE**, a S. W. central county of Texas, watered by affluents of the Colorado; area 925 sq. m.; pop. in 1870, 3,566, of whom 77 were colored. It has a hilly surface, about one tenth of which is suitable for farming, while the remainder furnishes good pasture. Iron ore, limestone, and coal are the important minerals. The chief products in 1870 were 15,588 bushels of wheat, 82,000 Indian corn, and 916 tons of hay. There were 880 horses, 20,024 cattle, 2,178 sheep, and 1,000 swine. Capital, Fredericksburg.

**GILLESPIE, William Mitchell**, an American author, born in New York in 1816. He died Jan. 1, 1868. He graduated at Cornell College in 1834, and spent nearly two years in Europe in travel and study. On his return to New York in 1845, he was appointed professor of civil engineering in Union college, which he held until his death. His works are: "Rome as seen by a New Yorker, 1843-'44" (1845); "Roads and Roads Manual for Road-making" (1845; 1871); "Philosophy of Mathematics" (1851); "Principles and Practice of Land Surveying" (1851); and "Treatise on Levelling, Topographical and Higher Surveying," edited by C. J. Smith.

**GILLIES, John**, a Scottish historian, born at Brechin, Forfarshire, Jan. 18, 1811. He died at Clapham, near London, Feb. 18, 1874.

was educated at the university of Glasgow, where he became professor of Greek. In 1778 he published a translation of the "Orations of Lysias and Isocrates." In 1786 he published in London his "History of Ancient Greece." In 1793, on the death of Dr. Robertson, he was made historiographer royal for Scotland. His principal works, besides those above named, are a "Translation of Aristotle's Ethics and Politics" (1804); the "History of the Ancient World from Alexander to Augustus" (London, 1807), which was afterward republished as the second part of his "History of Greece;" and a "Translation of Aristotle's Rhetoric" (1823).

**GILLIFLOWER**, the trivial name of the garden species of *mathiola*, usually called stocks by the florists, and sometimes stock gilliflowers and gillies. The name gilliflower has a curious origin: the French applied to this and other spicy-smelling flowers the term *giroflee*, clove-

Gilliflower (*Mathiola incana*).

scented; this, through the old spellings of *gyllifer* and *gyltfe* (with the *o* long), has become our gilliflower. Florists divide the plants into ten weeks, intermediate, Brompton, and emperor stocks, and each of these into several subdivisions. The ten-weeks and intermediate stocks are annuals, and are garden varieties of *M. annua*, a native of the seacoast of Europe, and a member of the large order *crucifera*; the flower in the wild state is reddish, but cultivation has produced a great variety of colors from pure white to dark purple; the seedsmen's catalogues present new varieties each year. The double varieties do not produce seeds, but such is the tendency to depart from the normal state that the seeds of single flowers will produce plants one half or more of which will be double; the seeds are imported from Germany, where great pains are taken in their production. The seeds of these varieties may be sown in the open ground when the soil becomes warmed, and treated as ordinary an-

nuals, or they may be sown in a hotbed, the young plants potted when large enough, and later turned out into the open border. Seeds may also be sown in August and September, and the young plants potted and kept over winter in a cool greenhouse, to be turned out

Double Gilliflower.

in spring. The Brompton stocks must be treated as biennials, as the original species, *M. incana*, is a biennial or a short-lived perennial. It does not endure our winters, and the plants must be potted and kept either in a frame or a light cellar until spring, or brought into bloom in the greenhouse or window during winter. Choice varieties may be increased by cuttings; and if the plant after flowering is headed back, it may be kept for several years.

**GILMORE, Quincy Adams**, an American soldier and engineer, born at Black River, Lorain co., Ohio, Feb. 28, 1825. He graduated at West Point in 1849, and served in the engineer corps and as assistant instructor at West Point till the outbreak of the civil war, when he distinguished himself by his services at Hilton Head, S. C. (1861), in the siege and capture of Fort Pulaski, Ga. (1862), and especially in the reduction of Forts Sumter and Wagner (1863-'4). He was made major general of volunteers July 10, 1863, resigned this commission Dec. 5, 1865, and now (1874) ranks as major in the corps of engineers, and is engineer in charge of the defences of the Atlantic coast. He has published "Siege and Reduction of Fort Pulaski" (New York, 1863); "Practical Treatise on Limes, Hydraulic Cements, and Mortars" (1863); and "Engineer and Artillery Operations against the Defences of Charleston Harbor in 1863" (1865).

**GILLOTT, Joseph**, an English manufacturer, born in Warwickshire about 1800, died in Birmingham, Jan. 6, 1872. He began life as a grinder of cutlery in Sheffield. Then he removed to Birmingham, and with the assistance of his wife began the manufacture of steel pens. It is said that he made them in a garret and sold them to small shopkeepers about the town.

They were the black "barrel" pens, and were very stiff and scratchy compared with the quills which they were intended to supersede. In 1820 Gillott made the first great improvement by cutting three slits instead of one, which gave an immediate impetus to the trade. Then by the introduction of machinery he greatly reduced the price, and by successive minor improvements made his pens still more popular, until he was able to build a large factory in Birmingham, and they were sold all over the world. The price of one steel pen when he entered business would buy 900 at the time of his death. His works now use five tons of steel weekly, and make 150,000,000 pens annually. Gillott acquired immense wealth, and was a connoisseur in the fine arts, having a celebrated gallery of paintings at his country residence, near Edgbaston.

**GILLRAY, James**, an English engraver and caricaturist, born in Chelsea about 1757, died in London, June 1, 1815. He was the son of a Chelsea pensioner, studied in the royal academy, and about 1784 became known as a successful engraver. Between 1779 and 1811 he published 1,200 caricatures, many of which were etched at once upon the copper without the assistance of drawings. The royal family and prominent cabinet ministers and politicians of the day were ridiculed by him without mercy. He died of delirium tremens. His works appeared singly, but a collection of them was published in London in 1830; an edition edited by Bohn in 1851; and a new and complete edition, with a "History of his Life and Times," by Thomas Wright, in 1874.

**GILMAN, Chandler Robbins**, an American physician, born at Marietta, Ohio, Sept. 6, 1802, died at Middletown, Conn., Sept. 26, 1865. During his childhood his father removed to Philadelphia. He took the degree of M. D. in 1824 at the university of Pennsylvania, and soon afterward removed to New York, where the whole of his active professional life was spent. In 1840 he was appointed professor of obstetrics and the diseases of women and children in the college of physicians and surgeons, to which was added in 1851 the subject of medical jurisprudence. In this chair Prof. Gilman continued until his death, although for the last year or two he was incapacitated by failing health. His principal publications were: a translation, prepared with the assistance of Dr. Theodore Tellkamp, of Bischoff's monograph "On the Periodical Discharge of the Ovum" (New York, 1847); "On the Relations of the Medical to the Legal Profession" (1856); and an edition of Beck's "Medical Jurisprudence" (Philadelphia, 1860).

**GILMAN, John Taylor**, an American statesman, born in Exeter, N. H., Dec. 19, 1753, died there, Sept. 1, 1828. On the morning after the news of the battle of Lexington and Concord reached Exeter, he marched with 100 other volunteers to Cambridge, Mass., where he served in the provincial army. Soon after,

his father being made treasurer of the office. In 1782 he was a delegate from New Hampshire to a convention which met at Hartford to measure for the defence of the country. In 1782 and 1783 he was a member of the continental congress, and in the latter year succeeded his father as treasurer of New Hampshire. He was one of the three commissioners appointed by the government of the United States to settle the accounts of the British in 1797 he was chosen governor, was reelected for 10 successive years, 1813, '14, and '15, after which he was not a candidate. He was a zealous lawyer and his popularity in New Hampshire was great that he was frequently chosen governor when his party was in the minority.

**GILMAN. I. Samuel**, an American clergyman, born in Gloucester, Mass., Feb. 16, 1781, died in Kingston, Mass., Feb. 9, 1858. He graduated at Harvard college in 1811, studied theology, and was tutor in mathematics at Cambridge from 1817 to 1819, when he married Miss Caroline Howard, and was ordained pastor of the Unitarian church in Cambridge, in which office he remained till 1840. He contributed many papers to reviews and other periodicals, on subjects connected with philosophy and general literature, and published in Boston a volume of "Contributions to Literature, Descriptive, Critical, Humorous, Biographical, Philosophical, Poetical." His other prose works are "Memoirs of a New England Villager" (1829), of which three editions were published; the "Pleasures and Pains of a Sunday" (1852). He translated the "Psalms" and published some original poems, which are the "History of a Rascal" and a poem read before the Phi Beta Kappa society of Harvard college. In Cambridge he took a prominent part in the temperance cause, as well as the intellectual culture.

**GILMAN. II. Caroline**, an American poetess, of the preceding, born in Boston, Mass. She is a daughter of Samuel Howard. At the age of 16 she wrote a poem "Jephthah's Rash Vow," which was published in the "North American Review." In 1819 she married the Rev. John Gilman, and removed with him to Charleston, S. C. She has published "Recollections of a New England Housekeeper," "Familiar Conversations with an American Matron," "Ruth Raymond's Progress," "Poetry of Travelling in the States," "Verses of a Young Man's Gift Book," "Original Poems" (1854), "The Sibyl, or Poets" (1854), and "Mother and Daughter" (1852). Since the war she has resided in Cambridge.

**GILMER. L. A. N. W.**, an American county, Virginia, watered by the Shenandoah river, area, 512 sq. m.; pop. 10,000.

27 were colored. It has a rough surface, much of which is thickly wooded, and a rich soil, suitable for grain and pasturage. There are several salt springs and iron mines. The chief productions in 1870 were 9,830 bushels of wheat, 106,036 of Indian corn, 17,592 of oats, 44,929 lbs. of butter, and 1,636 tons of hay. There were 1,114 horses, 1,295 milch cows, 1,697 other cattle, 6,100 sheep, and 3,907 swine. Capital, Glenville. II. A N. county of Georgia, drained by Coosawattee and other rivers; area, about 500 sq. m.; pop. in 1870, 6,644, of whom 117 were colored. Several spurs of the Blue Ridge, abounding in beautiful scenery, and alternating with fertile valleys, traverse parts of the county. The mineral products, comprising gold, marble, and iron, are valuable and abundant. The chief productions in 1870 were 8,103 bushels of wheat, 10,417 of rye, 169,099 of Indian corn, 12,333 of oats, 13,546 of sweet potatoes, and 67,128 lbs. of butter. There were 764 horses, 1,922 milch cows, 3,369 other cattle, 6,461 sheep, and 10,701 swine. Capital, Ellijay.

**GILOLO**, or **Halmahera**, an island of the Indian archipelago, in the Molucca group, between Celebes and New Guinea, separated from the former by the Molucca passage and from the latter by Gilolo strait; area, about 5,780 sq. m.; pop. estimated at 27,000. It is crossed by the equator, and lies between lat. 2° 30' N. and 1° S., and lon. 127° and 129° E. The outline somewhat resembles that of Celebes. The island consists of four peninsulas radiating from a centre situated in about lat. 0° 40' N. Of these peninsulas two trend N. and S. respectively, along or near the 128th meridian; one extends toward the N. E.; and the fourth stretches to the S. E., terminating in Cape Tabo, the most easterly point of the island. The length of Gilolo is nearly 250 m. The range of smaller islands to which the name Moluccas was originally applied, including Ternate, Tidore, Morty, Makian, and Batchian, skirts the southerly part of the W. coast. Gilolo is of volcanic formation. From the sea coast, which is itself described as in many parts mountainous, lofty mountains are visible in the interior, some of which are said to be volcanoes. According to Wallace, the surface seems to have undergone changes of elevation within a recent period; and the upheaval of a mountain at Gamakonora in the northern peninsula is reported to have occurred in 1673. Fringes of coral reef interfere with navigation along many portions of the coast. The inland regions are but very slightly known; they appear to consist largely of elevated tracts of forest. The clove tree is indigenous to the island. About four fifths of the inhabitants are ruled by the sultan of Ternate, whose residence was formerly at the town of Gilolo, on the W. coast of the northern peninsula. The Malay element predominates, but the active and energetic inhabitants of the northern peninsula belong to an indigenous race called Alfuros, differing

both from the Malays and the Papuans, yet possessing some of the characteristics of each. The government of the Netherlands maintains an insignificant military station at Dodingo, a village opposite Ternate. The principal products of Gilolo are sage, spices, tortoise shell, and tropical fruits.

**GILPIN**, a N. central county of Colorado, lying chiefly in the foot hills; area, about 150 sq. m.; pop. in 1870, 5,490. The average altitude of the county is about 9,000 ft., but the climate is mild. The surface is broken by mountain ranges. The valleys, watered by small streams, are fertile. It is one of the richest gold-mining regions in the world, and contains more than 90 quartz mills. In 1870 it produced bullion to the value of about \$2,000,000. There are 9 hotels, 6 churches, 5 schools, 2 foundries, 2 smelting works, 1 chlorine reduction establishment, and 2 newspapers. The chief agricultural productions in 1870 were 21,665 bushels of potatoes and 172 tons of hay. Capital, Central City.

**GILPIN, Bernard**, an English ecclesiastic, born in Kentmire, Westmoreland, in 1517, died in Houghton, Durham, in 1583. He was educated at Oxford, became a convert to Protestantism after a disputation with Peter Martyr, and in 1552 was made vicar of Norton in the diocese of Durham. On the accession of Mary he went abroad for three years. On his return his uncle, Dr. Tunstall, bishop of Durham, appointed him his archdeacon, and gave him the living of Houghton, of which he remained rector till his death, declining the bishopric of Carlisle, which was offered to him by Queen Elizabeth. His parish and the neighboring neglected parishes, which he regularly visited, comprised a wild rugged district on the Scottish border, whose inhabitants, from centuries of marauding warfare, were in a half savage state. He went fearlessly among them, and by his preaching and benevolence acquired great influence over them. He preached so boldly against the vices of the times, and especially of the clergy, that complaints were made against him successively to the bishop of Durham and the bishop of London. He built and endowed a grammar school in his parish for the instruction of the children of the poor, and regularly educated at his own house 24 lads of promise whom he ultimately sent to the university. His life has been written by George Carleton (London, 1628), and by William Gilpin (London, 1751).

**GIN**, or **Geneva** (Fr. *genièvre*, juniper), an alcoholic liquor, distilled generally from rye and barley and flavored with juniper. It was made originally in Holland, whence it is sometimes called "hollands," and it is still manufactured largely at Schiedam, Gouda, and Amsterdam. In the distilleries of Schiedam two parts of unmalted Riga rye are used to one part of malted bigg or barley. This is mashed with water, at a temperature of from 162° to 168°, in the proportion of 36 gallons to every

1½ cwt. of meal. When the magma has been made uniform by stirring, the tun is covered to confine the heat, and it is left thus for two hours. It is then stirred up again, the transparent spent wash of a preceding mashing is added, and afterward cold water enough to reduce the temperature to 85°. Flanders yeast is introduced next, in the proportion of 1 lb. to every 100 gallons of the mixture. Fermentation speedily sets in, and the attenuation is complete in from 48 to 60 hours. A part of the yeast is usually skimmed off from the fermenting tun, by which the production of spirit is obstructed, but the quality of the liquor is improved by preventing its impregnation with yeasty particles. The wash and grains are then transferred to the still and converted into low wines, into every 100 gallons of which are put two pounds of juniper berries and about a quarter of a pound of salt. The whole is then put into the low-wine still and the spirit drawn off by a well regulated heat. The quantity of spirit varies from 18 to 21 gallons to the quarter of grain. There are 300 distilleries of this liquor at Schiedam. English gin, manufactured largely in London and other places in Great Britain, is made usually from the impure products of the distillation of Scotch and English whiskey, rectified by one or more distillations, and flavored with various substances, such as the oil of turpentine, oil of juniper, coriander seeds, cardamoms, capsicum, &c. This gin is the common alcoholic drink of the lower classes in England, and almost every London dealer has his private receipt for increasing its pungency and strength. It is adulterated probably more than any other liquor. Pure gin contains, according to Brande, 51.60 parts of alcohol in every 100 parts.

**GINDELY**, Anton, a German historian, born in Prague, Sept. 8, 1829. He became in 1853 professor of the German language and literature at the Bohemian *Oberrealschule* in Prague, and in 1862 of Austrian history in the university of that city and archivist of Bohemia. He has published many historical works, including *Rudolf II. und seine Zeit* (2 vols., Prague, 1862-'5), *Monumenta Historiæ Bohemica* (4 parts, 1864-'7), and *Geschichte des Dreissig-jährigen Kriegs* (1869).

**GINGER**, the scraped and dried rhizoma of *zingiber officinale*, a plant of the order *zingiberaceæ*, a native of Hindostan, but cultivated both in the East and West Indies, and in Sierra Leone. It has a tuberous root, an annual stem 2 or 3 ft. high, and smooth, lanceolate leaves, 5 or 6 in. long. Its flowers are yellowish and emit an aromatic odor. Its medicinal virtues reside in its root, of which two varieties are found in the market, the black and the white or Jamaica ginger. The difference is chiefly in the retention or removal of the epidermis, and perhaps a subsequent bleaching process applied to the lighter variety. In commerce the whole ginger is called race ginger. A preserve is made by boiling the young and

tender roots in sugar; large quantities imported from China. Ginger is used in cooking and as a medicine. Its odor is strong and characteristic, its taste spicy and pungent. It contains a volatile oil and resins, and other constituents of less importance, and

Ginger (*Zingiber officinale*).

many official preparations, its virtue usually extracted by alcohol; but an infusion may be used. The popular aromatic sold as extract of Jamaica ginger is a tritiated alcoholic tincture. Ginger is a stimulant and carminative, either alone or in combination with the alimentary canal. It will relieve flatulence and the griping pains of a mild dysentery. It renders bitter infusions and tinctures acceptable to the stomach, and may be advantageously combined with tonic powders. In many cases it palliates, if it does not cure, the distress of seasickness. The dose of ginger is 10 grs. or more; the fluid extract and tincture are the best form for administration.

**GINGKO** (*Salisburia adiantifolia*), a tree from China and Japan, belonging to the suborder of *coniferae*. No tree bears less like a member of the pine family than the ginkgo; it is a rapid grower, the trunk clothed with a light gray bark, the deciduous leaves are alternate, wedge-shaped, with the broad end at the base, or cut more or less deeply, 3-lobed, thick and leathery, with distinct ribs, and of a light yellowish green. The leaves are so like those of the hair ferns that it is by some called the hair tree. The staminate flowers are borne upon separate branches in slender catkins about 1½ ft. long. The female flowers are either solitary or in clusters at the ends of the branches, each flower, which consists only of a small cup-like disk; the ovule is seated in a small cup-like disk;

in size and covers the base of the ripe fruit, which is a globular or ovate nut. In its native countries the ginkgo attains a large size; Bunge mentions one 40 ft. in circumference and still vigorous; a specimen in the botanic garden at Pisa is 75 ft. high. It is supposed that it was introduced into Europe from Japan by the Dutch; it was first planted in this country in 1784 by Mr. Alexander Hamilton, who lived near Philadelphia; the trees are still standing, though the grounds have been converted into a rural cemetery; there are also some fine specimens in Boston. The wood is of a yellowish color without any resinous qualities, and useful as lumber, though the Chinese cultivate the tree mainly for its nuts, which are edible but insipid; medicinal virtues are attributed to them, and they are considered essential, roasted or boiled, at entertainments. Though the tree was for many years regarded as a great rarity in the United States, it is now not uncommon in cultivation, and is used in the ornamentation of lawns and pleasure grounds; it

Ginkgo (*Salisburia adiantifolia*).

should be planted where the peculiarity of its foliage can be readily observed. By frequently heading back the branches, it can, if desired, be kept in the form of a large bush. As it is perfectly hardy at Boston, it will probably endure the climate in most parts of the country. It is raised from seeds, cuttings, and layers; it has not fruited to any great extent in this country, but has done so abundantly, in Europe, and the seeds are imported by seed dealers. Cuttings of the old wood or of the partly ripened new wood take root readily, as do layers. Trees grown from cuttings and layers are not likely to be so well shaped as those obtained from seed. Ginkgo is one of the Chinese names for the tree, and was adopted by Linnaeus as the generic name; he described it in 1771 as *ginkgo habuba*, but Sir James Edward Smith, considering the name "uncouth and barba-

rous," in 1796 altered it to *Salisburia*, in honor of R. A. Salisbury, an English botanist; the specific name recognizes the resemblance of the leaves to the fronds of *adiantum*, the maiden-hair fern. Although this change of name was against the rules of scientific nomenclature, and strongly protested against at the time, later botanists have generally adopted it.

• **GINGRAS**, a N. E. co. of Dakota territory, recently formed, and not included in the census of 1870; area, about 1,450 sq. m. Dakota or James river rises here, and Cheyenne river flows through the N. part.

**GINGUENE, Pierre Louis**, a French historian, born in Rennes, April 25, 1748, died in Paris, Nov. 16, 1816. He went to Paris in 1772, being then acquainted with classical, French, Italian, and English literature, and music. He had written before leaving Rennes a poem entitled *La confession de Zulmé*. He showed it to many of his friends, copies were taken, and in 1777 it was published without his consent and disfigured by innumerable errors. Several persons claimed the authorship, and he finally published it correctly under his own name in 1779. He afterward published several other poems. In 1776 the celebrated composer Piccini arrived in Paris, and soon after a violent quarrel broke out between his admirers and those of Gluck, in which Ginguene was the most effective supporter of Piccini's cause. About 1780 he obtained a clerkship in the office of the minister of finance. The moderation of his views brought upon him the hostility of the revolutionists, and in 1793 he was thrown into prison, and only released on the overthrow of Robespierre. He was soon after appointed a member of the executive commission of public instruction, and was director general of that branch of the administration from 1795 to 1797. In 1794, in company with Chamfort, he commenced the *Décade philosophique littéraire et politique*. After the abolition of the republican calendar the title was changed to *Revue*, and he continued to write for it till 1807, when it was merged in the *Mercur de France*. In 1798 he went to Turin as minister plenipotentiary, but remained only seven months. In 1799 he was chosen a member of the tribunate. His course there, especially his opposition to special tribunals, excited the anger of Bonaparte, and he was removed from the office in 1802. In 1802-'3 and 1805-'8 he delivered lectures on Italian literature at the athenæum of Paris, which attracted crowded audiences, including a large number of the most distinguished literary men of France. He was a member of the commission established to continue the *Histoire littéraire de la France*, of which 12 volumes had been completed by the Benedictines; to the succeeding volumes he contributed many articles, mostly on the lives and productions of the troubadours. He also wrote much for the *Biographie universelle* and the *Moniteur*. But his great work is the *His-*

in America," "First Snow," "Winter in Vermont," and "Bernese Alps by Sunrise." Since 1870 he has lived in France.

**GIGOUX, Jean François**, a French painter, born in Besançon in 1806. He is said to have been originally a blacksmith, and became famous in 1835 by his "Death of Leonardo da Vinci." In 1850 he exhibited "The Dead Christ" and "The Death of Cleopatra," and in 1852 "Galatea," which he has also engraved. One of his largest works, executed for the council of state and representing "Charlemagne dictating his Capitularies," was burned in 1871.

**GIJON**, a seaport of Asturias, Spain, on the bay of Biscay, in the province and 15 m. N. N. E. of the city of Oviedo; pop. about 10,500. It is built on a low headland, surmounted by a hill. Some ancient walls surround the upper or old town, and a fortress and batteries guard the new town, which reaches down to the shore. The former Augustinian convent is used as a cigar manufactory, employing 1,400 persons. There are active fisheries, and some coasting trade. The harbor is safe, though not easily accessible. The first quay was built here under Charles V. in 1552-4, and a new one was constructed in 1768. The Spanish armada was repaired here in 1588. In 1810 the town was sacked and its shipping destroyed by the French, under Bonnet.

**GILA**, a river of New Mexico and Arizona, the principal tributary of the Colorado river of the West. It rises in the Sierra Madre mountains in Socorro co., New Mexico, flows S. W. to near the Arizona boundary, where it bends S. and then pursues a general W. course through that territory to its junction with the Colorado, about 180 m. above its mouth. Its sources are about 5,000 ft. above the sea. The principal tributaries from the north are the Rio Nutroso, Prieto, Bonito, San Carlos, Salt river or Rio Salado, and Agua Fria creek; from the south the Rio San Domingo and San Pedro. The Santa Cruz river, after a course of nearly 100 m., is lost in the sands of the desert, and seldom discharges its waters into the Gila. For more than half its entire length, which is nearly 500 m., the Gila passes through mountains, and in some places is unapproachable, being buried between walls of perpendicular rock nearly 1,000 ft. high. It emerges from the mountains in lon. 111° 25' W., after which its course is through an open and comparatively level country to its termination. In the last 300 m. it has an average fall of 5 ft. per mile, and averages 60 ft. in width, 3 ft. in depth, and in velocity 2 m. an hour. In the lower portion the valley is from 1 to 3 m. wide; about 150 m. from its mouth there is a considerable bend to the north, where the valley for 25 m. is from 5 to 10 m. wide. The valley is in many places covered with mezquite and cottonwood, and on its margin with the willow. Several varieties of cactus, including the pitahaya (*cereus giganteus*), grow on the table land near the river, but never in the alluvial lands in its valley.

The ruined edifices, broken pottery, and traces of irrigating canals found along this river show that its former population was much larger than at present. One of these structures is three stories high and in good preservation. The others are in a ruined state, and present little more than dilapidated walls, tumuli, mounds, &c., of crumbling adobe, of which the buildings were constructed. (See *CASA GRANDES*.) About 200 m. from the Colorado, in one of the finest portions of the valley, is the reservation of the Maricopa and Pima Indians. It is intersected in all directions by irrigating canals, and produces abundant crops. Further E., among the mountains, are many luxuriant valleys where once existed a considerable population, as is evident from the traces of cultivation and the ruins which remain.

**GILBERT, Sir Humphrey**, an English navigator, half brother of Sir Walter Raleigh, born at Dartmouth in 1539, lost at sea about the end of 1583. He was educated at Eton and Oxford, followed the military profession, and was knighted in 1570 for his services in Ireland. Being interested in geographical discovery, both from love of fame and of adventure, he sailed in 1583 with five vessels and 260 men, prepared to take possession of the northern parts of America, and founded a colony in Newfoundland, which, however, did not prove permanent. On the return his vessel, of only 10 tons burden, foundered, and all perished. He published a book in 1576, "A Discourse of a Discovery for a new Passage to Cathay," to prove the possibility of a N. W. passage.

**GILBERT, Sir John**, an English painter, born in 1817. He exhibited in 1836 a water-color drawing, "The Arrest of Lord Hastings," in the Suffolk street gallery, and an oil painting in the royal academy. In 1839 he first exhibited in the British institution, where he has been represented almost every year since. He has made many illustrations for books and pictorial newspapers, especially for the British classics, concluding with an edition of Shakespeare, and for the "Illustrated London News." In 1852 he was elected an associate, in 1853 a member, and in 1871 (when he was knighted) president of the society of painters in water colors. He is an associate of the royal academy, and honorary president of the Liverpool society of water-color painters. His best known oil paintings are "Don Quixote giving advice to Sancho Panza," and other subjects from Cervantes; "The Education of Gil Blas;" "A Scene from Tristram Shandy;" "Othello before the Senate;" "The Murder of Thomas à Becket;" "The Plays of Shakespeare," a tableau introducing the principal characters in each play; "Charge of Cavaliers at Nanby;" "A Drawing-room at St. James's;" "A Regiment of Royalist Cavalry;" "Rubens and Teniers;" "The Studio of Rembrandt;" "Wesley and Buckingham;" "A Convocation of Clergy;" and "The Entry of Joan of Arc into Orleans."

**GILBERTINES**, an English religious order, so called from the founder, St. Gilbert of Sempringham (born in 1083, died Feb. 4, 1189). They were also called the "Order of Sempringham." Gilbert, who was by birth lord of Sempringham and Tirington, had become as a priest pastor of both places. He first built a convent near the church of St. Andrew for seven poor maidens, which became so flourishing that he was called upon to establish several others in various parts of the kingdom. Having in vain endeavored to unite these houses to the order of Cîteaux, Gilbert built a monastery of canons regular near each convent, gave to the canons the rule of St. Augustine, to the nuns that of St. Benedict, and placed the lay brethren who served them under the rule of Cîteaux. This order with its constitutions was approved by Eugenius III., and confirmed by his successors. It numbered at the founder's death 13 double convents, besides hospitals for the sick and asylums for widows, orphans, and the poor, with 800 monks and upward of 1,200 nuns. The Gilbertines were confined to England. Sempringham afforded an asylum to Thomas à Becket during his quarrel with Henry II. At the suppression of monasteries under Henry VIII. the order possessed 21 houses and 11 double convents. The Gilbertine rule is given in full by Holstenius. See also Hurter, *Geschichte des Papstes Innocenz III. und seiner Zeitgenossen*.

**GILBERT ISLANDS**, or **Kingsmill Group**, a cluster of coral islands in the Pacific, on both sides of the equator, between lon. 172° and 174° 30' E.; pop. estimated at 60,000. The largest are Taputeonea or Drummond, and Tarawa or Cook islands, the former 30 m. long by about  $\frac{1}{2}$  or  $\frac{3}{4}$  m. wide, and the latter 20 m. long. Almost the only cultivated products are the cocoanut and pandanus, which form the staples of food, and a species of taro (*arum cordifolium*), highly prized by the natives. The breadfruit is found on the northern, though not on the southern islands. The climate is equable, and though warm is not very oppressive. The inhabitants resemble the Malays. The people are divided into three classes, chiefs, landholders, and slaves. There is no general authority recognized throughout the group, but there are several kings, one of whom rules over three of the islands, while others are scarcely respected in any. In some places the government is administered by public assemblies. The islanders are fond of war and prone to suicide, but they are kind to their children, generous, hospitable, and more considerate of women than is usual among savages. They are said to eat human flesh occasionally, but are not habitual cannibals. Their clothing is made of the leaves of the pandanus; their houses and canoes, though constructed of rude materials, are superior in size, strength, and elegance to any others in the Pacific. The islands have several good harbors, but are seldom visited by vessels.

**GILBOA**, a mountain in Palestine, between the river Jordan and the plain of Esdraelon, the scene of the defeat and death of Saul and Jonathan. The name Gilboa signifies a bubbling fountain, and was probably taken from a large fountain at the northern base, called in Scripture the well of Harod, or the fountain of Jezreel. The ancient name is preserved in the village on the mountain, called now Jelbun, and in the time of Jerome Gelbus. The fountain is now known as Ain Jalud. The mountain rises not more than 600 ft. above the plain, but extends E. and W. about 10 m. Its sides are white and barren. Near the fountain of Jezreel was the ancient city of that name, and at this place the Israelites encamped before the battle; while the Philistines pitched at Shunem (now Solam), 8 or 10 m. north, upon the opposite rising ground. The battle was fought, according to the common chronology, in the year 1055 B. C.

**GILDAS**, surnamed "the Wise," a British historian, born, according to some authorities, in 493, according to others in 511, died in 570 or 590. He was the son of Caw, a British prince who emigrated to Wales to avoid subjection to the Anglo-Saxons, and the Welsh bard Aneurin is supposed to have been the same person or his brother. (See ANEURIN.) His only complete work extant is a short Latin composition on British history, entitled *De Calamitate, Excidio et Conquestu Britannia*, in which he mourns over the ruin of his country, and inveighs against the British kings and clergy. It was first published by Polydore Vergil in 1525, and has been often reprinted. The best edition is by Stevenson, under the care of the English historical society (London, 1838). Translations have been published by Habington (1638), and by Dr. Giles in "Bohn's Antiquarian Library" (1848). It is said by Wright that there is no independent authority for the existence of Gildas, or for the historical truth of the work attributed to him, which he regards as a forgery of the 7th century.

**GILDEMEISTER, Otto**, a German writer, born in Bremen, March 13, 1823. He studied at the university of Bonn, and became in 1845 connected with and in 1850 editor-in-chief of the *Weserzeitung*. In 1852 he was chosen secretary of the Bremen senate, in 1857 senator, in 1866 representative in the diet of the North German confederation, and in October, 1871, burgomaster. He has translated into German the complete works of Byron (6 vols., Berlin, 1864), and many plays of Shakespeare for Bodenstedt's complete edition; and his version of Shakespeare's sonnets was published in 1871.

**GILDING**, the covering of the surfaces of bodies with a thin coating of gold. This method of economizing the precious metal, and imparting to solid bodies the appearance of being wholly composed of it, was practised at very remote periods. The sacred books allude to it; in Exod. xxvi. 29 there is a com-

charging both of these philosophers with tendencies to pantheism; *Del buono* (1843), in which he applies his philosophical system to ethics; *Apologia del libro intitolato Il Gesuita moderno* (Paris and Brussels, 1848); and *Opere politiche* (2 vols., Lugano, 1851). A uniform edition of his earlier works was published at Brussels (9 vols., 1843-'5). The edition of his posthumous works, edited by G. Massari (Paris and Turin, 1856), has never been completed.

**GIOCONDO**, or *Jocundus*, *Fra Giovanni*, an Italian architect, born in Verona about 1450, died in Rome about 1530. He was a Dominican friar, studied archæology in Rome, and collected in that city upward of 2,000 ancient inscriptions, which he presented to Lorenzo de' Medici. He designed the fortifications of Treviso, saved the lagoons of Venice from inundation by diverting the waters to the sea near Chioggia, and in 1494-'8 was architect to the emperor Maximilian at Verona, where he built the palace of the council and the church of Sta. Maria della Scala. In 1500-'7 he was employed by Louis XII. in building the bridges (since restored) of Notre Dame and of the Hôtel Dieu. He afterward constructed in Venice a great warehouse on the rialto, known as the Fondaco de' Tedeschi, for which Titian and Giorgione made decorations; but the greater part of it being destroyed by fire in 1514, he left Venice because the authorities, instead of permitting him to rebuild it in stone, ordered another structure of wood by an inferior architect. Bramante dying in the same year, Giocondo was appointed by the pope to succeed him as architect of St. Peter's, and labored on that grand edifice simultaneously with Raphael. He instructed Scaliger in Latin and Greek, and was proficient in philosophy, theology, and classical literature. Having been the first to prepare a design of Julius Cæsar's bridge across the Rhine, he wrote notes on the latter's "Commentaries," which were issued in 1517 by Aldus Manutius the elder, who also published (1508-'14) Pliny's correspondence with Trajan, which Giocondo had discovered while in Paris.

**GIOJA**, or *Gioja dal Colle*, a town of Italy, in the province of Bari, situated on the crest of the E. branch of the Apennines, on the road from Bari to Taranto, 18 m. E. by S. of Altamura; pop. in 1862, 17,005. It derives great prosperity from the rich local products of cereals and oil. The outskirts were in former times covered with woods, which the emperor Frederick II. enclosed for a park.—There is also a town of Gioja on the W. coast of Calabria, which gives its name to a gulf.

**GIOJA, Flavio.** See COMPASS, vol. v., p. 186.

**GIOJA, Melchiorre**, an Italian political economist, born in Piacenza, Sept. 20, 1767, died in Milan, Jan. 2, 1829. He studied in his native city at the college Alberoni, and received holy orders. He lived in retirement till the changes caused in Italy by the victories of Napoleon. The institute of the Cisalpine republic

having proposed the question, "What free governments is the best for Italy," he answered, "The republican," in which obtained the prize. He was subsequently appointed historiographer of the state. His liberal views caused him a temporary imprisonment in 1799. Having lost his position as historiographer by a treatise on liberty and been removed from the board of administration on account of articles criticising the management of public affairs, he revenged himself by a sarcastic article entitled *Il potere*, the consequence of which he was obliged to leave Italy. He was recalled after a year and entrusted with the elaboration of a constitution for the kingdom of Italy. Suspected of participation in the liberal movements, he was arrested by the Austrian government, set free after eight months' imprisonment, was a disciple of Bentham and Locke, and wrote numerous works on political economy, the best in the Italian language.

**GIORDANO**, *Luca*, an Italian painter, born in Naples in 1632, died there, Jan. 12, 1705. He studied at first under Ribera, and went to Rome and studied under Pietro Cortona. He painted with much rapidity; which circumstance, as well as the name of *Fa Presto*, was perhaps the cause of the avarice of his father, an inferior painter. Luca's youth sold his works at a low price, and was continually urging him to go to Rome, words, *Luca, fa presto* ("Luca, make haste"). He visited Parma, Venice, Bologna, and Rome, leaving everywhere prodigies of talent, ease, and facility. Invited to Spain by Philip II., he remained in Spain a few years, and executed an immense number of works in the Escorial, and in the churches and palaces of Madrid, Toledo, &c. The manner in which he imitated the manner of Raphael gained him the title of the *Protettore*. Among the most admired of his works are the "Triumph of the Virgin" in the Escorial, the "Virgin and Child Jesus" in the Pitti palace, and the "Judgment of Paris."

**GIORGIONE** (*GIORGIO BARBARO*), one of the founders of the Venetian school of painting, born at Castelfranco, near Venice, in 1477, died of the plague in 1511. According to Lanzi, his natural grandeur conferred upon his art more boldness of mind than of force. He was in the school of the Florentines, but Titian was one of his followers, following the bent of his own mind, and from their stiff and formal style formed a style of his own, characterized by boldness of outline, grace in the countenances as well as in the figures, well graduated, and an effective chiaroscuro, probably acquired by studying the works of Leonardo da Vinci, and the style of Correggio.

of any other Italian painter. Giorgione's works in fresco, of which he executed many on the façades of Venetian palaces, are almost entirely obliterated, but his portraits in oil, among the most admirable ever painted, and remarkable for the warmth of their coloring, particularly in the flesh tints, as well as their grace and animated expression, are in good preservation, although they are not numerous. Of his historical paintings, the "Moses rescued from the Nile," in the Pitti palace at Florence, is esteemed his *chef d'œuvre*.

**GIOTTO**, called also **GIOTTO DI BONDONE** from his father, and by some **AMBROGIOTTO**, the regenerator of Italian art, born at Vespignano, near Florence, in 1276, died in the latter place about 1337. Tradition relates that the painter Cimabue discovered him, a shepherd boy in the valley of Vespignano, in the act of drawing upon a smooth piece of slate the figure of a sheep grazing near him, and was so struck with the genius which the work evinced that he took him into his own house in Florence and taught him his art. Giotto speedily excelled his master, who undoubtedly at the close of his life conformed his style to that of his pupil. Art was then feebly struggling to free itself from the trammels of the Byzantine style. Cimabue and Duccio di Siena had indeed attempted to improve on existing models, but Giotto rejected them altogether. The symbolic representation of a subject, according to conventional rules, had hitherto been the highest aim of the artist. Giotto first gave life to art by making his works truly reflect nature. From the remoteness of the epoch in which he painted, it is not surprising that many of his works have perished; but from the specimens that remain and the traditions of those that are lost it is easy to account for his influence over central Italy, from Padua to Naples. Social and political revolutions, the quality of the materials used, the effects of climate, and the vandalism of his own and of later times, have destroyed or hopelessly injured his choicest works. Some of them have been whitewashed over, among them his portraits of Dante and other eminent citizens of Florence, one of his earliest works painted on the walls of the chapel of the Podestà, now the Bargello or prison in Florence, which Mr. Richard H. Wilde and Mr. Bezzi brought to light in 1840. These are said by Vasari to be the first successful attempts at portraiture. The record of Giotto's life is not very clear, but it is certain that before the death of Cimabue his reputation was such that Pope Boniface VIII. summoned him to Rome, where he designed his famous mosaic of the *Nativity*, representing the disciples at sea in a tempest and Christ raising Peter from the waves. It is now in St. Peter's, but frequent restorations have left little of the original work besides the composition. We next hear of him at Padua, where about 1306 he executed in the chapel of the Madonna dell' Arena his 42 paintings representing the life of the Virgin. He here

met his friend Dante, then exiled from Florence, to whose influence the allegorical tendency which these and many of his subsequent works exhibit is justly ascribed. An instance of this is afforded in the majestic figures of Poverty, Chastity, and Obedience, representing the three vows of the order of St. Francis, over whose tomb they are painted in the famous abbey church of the Franciscan order at Assisi, the repository of so many curious specimens of old Italian art. Robert of Naples entertained him honorably at his court, where he painted the sacraments for the Incoronata; and he is even said to have followed Clement V. to Avignon, and to have painted there and elsewhere in France. The wonder and enthusiasm which his works excited are perhaps without a parallel in the history of Italian art. A contemporary writer naïvely illustrates the feeling of the time by expressing his surprise that in Giotto's pictures "the personages who are in grief look melancholy, and those who are joyous look gay." Boccaccio says that "through Giotto that art was restored to light which had been for many centuries buried." Giotto excelled also in sculpture and architecture. The famous Campanile of Florence, erected in 1334, was from his designs. His school flourished for upward of a century after his death.

**GIOVIO, Paolo** (*PAULUS JOVIVS*), an Italian Latin historian, born in Como, April 19, 1483, died in Florence, Dec. 11, 1552. He studied at Pavia, abandoned medical for historical inquiries, was protected by Popes Leo X. and Clement VII., by Charles V. and Francis I., wielded a venal pen, was loaded with honors and favors, and having lost all that he possessed when in 1527 Rome was sacked by the army of the constable of Bourbon, was rewarded with the bishopric of Nocera. His most important work is a "History of his own Time" in 45 books, 6 of which are wanting. His veracity is not to be relied on.

**GIRAFFE**, or **Camelopard** (*giraffa camelopardalis* of most authors; *cervus camelopardalis* of Linnaeus), an African genus of the ruminants, with persistent horns, common to both sexes, having but a single species, as above. The characteristics of this singular animal, which appears, in some particulars, to participate in the qualities of the camel, the ox, and the antelope, are these: The lip is not grooved, is entirely covered with hair, and is very much produced before the nostril; the tongue is extremely long and prehensile, capable of being protracted or retracted at will, and of being tapered so as to enter the ring of a small key; the neck is very long, the body short, hind part lower; false hoofs none; tail elongate, with a tuft of thick hair at the end. The horns constitute the principal generic characteristic, since they are of neither the bovine nor cervine form, but are in fact bones, exhibiting throughout precisely the same structure as the other bones, united to the frontal and parietal bones by a distinct suture, covered with a hairy skin,

and terminating in a ring of bristly hairs at the summit, surrounding a bare apex. These bristles, according to some naturalists, want only the gluten to cement them into true horns, and embody the animal in the systematic arrangement of the *cacicornia*. The giraffe is assimilated to the camel by the length of its neck, by the callosities on its chest and knees, and by its having no false hoofs; to the other ruminants by the structure of its stomach and digestive organs generally, and by its non-possession of the reticulated water bag. To the antelopes it is assimilated by the fact that the coils of its colon are spiral, and that its cæcum is simple. With the solid-horned deer, which shed and renew those appendages annually, it is connected by the assumed fact of its having no gall bladder. In its dental system, the giraffe offers the same formula with the deer, goat, antelope, sheep, and ox, namely: incisors  $\frac{1}{2}$ , canines  $\frac{1}{2}$ , molars  $\frac{1}{2} = 32$ . The pos-

Giraffe (*Giraffa camelopardalis*).

trils are provided with cutaneous sphincter muscles, and can be shut at will like the eyes. The eyes are beautiful, extremely large, soft and brilliant, and are so placed that the animal can see much of what is passing on all sides and even behind it. Thus it is approached with the greatest difficulty; and if surprised or run down, it can direct the rapid storm of kicks by which it defends itself in the most accurate manner. Its horny hoofs are divided, and it wants the two small lateral toes generally seen in the true ruminants, from which this again distinguishes it. The immense length of its legs and height at the withers, raising the insertion of the neck so far from the ground that the animal can graze on an even surface only with difficulty and by straddling the fore legs wide apart, enables it to feed on what it prefers as food, the delicate and succulent leaves and twigs of the tallest trees, particularly those of a spe-

cies of acacia peculiar to the districts which it inhabits. The peculiar conformation of tongue, which is furnished with rough papillae capable of voluntary erection, enables it to gather and collect into little bundles the leaves which it likes. Its speed, which is far from contemptible, is shown by the state of hunters who have pursued it, particularly Capt. Gordon Cumming; all of whom, that, being timid and wary, and always requiring a good start, it is not easily overtaken except by a swift horse. Its pace is a paco with both legs moved on the same side, and a regular gallop, by changing from one to the other of which, with no apparent diminution of its speed, it can keep up a considerable rate of going for a long continued time distance. Le Vaillant, the first well informed modern zoölogist who saw it in a state of nature, asserts that he "knows beyond a doubt that by its kicking it often tires out, discards, and even beats off the lion." This is shown by Capt. Cumming. Of the habits of the giraffe to the country and places it inhabits, this observant naturalist and sportsman speaks as follows: "I have often noticed a remarkable resemblance between it and the general appearance of the lion which it is found. . . . And as the giraffe is invariably met with among venerable trees where innumerable blasted and weathered trunks and stems occur, I have been in doubt as to the presence of a lion until I had recourse to my spy-glass: on referring the case to my savage attendants, I have known even their optics to fail, time mistaking the dilapidated trunks for leopards, and again confounding real leopards with those aged veterans of the forest. This animal when full-grown attains a height of 15, 16, and even 17 feet. It was formerly believed almost universally that its legs are much longer than the hinder legs, in fact, taking the legs only from the hip, the hind legs are the longer by about one-fifth. The great development and height of the withers, to give a proper base to the long and towering head, have been a common error. The color of the giraffe is a rich chestnut-brown in intensity and in the mode of its distribution. The head is generally of a uniform brown; the neck, back, and sides, the shoulders and thighs, are varied with tessellated, dull, rust-colored marks of a diamond form, with white narrow divisions; on the sides the marks are less regular; the belly and legs are whitish, faintly spotted; the part of the tail next to the body is covered with smooth hair; its trunk is very slender, toward the end the hairs are very long and coarse, and form a great tuft beyond the tip of the tail. The color of the female is less vivid than that of the male, she is somewhat smaller, and has the protuberance of the frontal bone less prominent, eyes, which by some writers has been

rudimental horn, less strongly developed than the male.—The giraffe has been long known to history. It is represented on the painted walls of the sekos of the Memnonium, discovered and described by Belzoni; and also on the celebrated Prænestine pavement, said to have been constructed by the orders of Sulla, who had served as quæstor in Numidia. It was exhibited in the *circus maximus* by Julius Cæsar, alive, for the first time in Europe, but was afterward a frequent spectacle at the cruel shows of Rome. Gordian, the third of the name, once exhibited 10 together. It continued to be known and described by travellers, but was not brought into Europe until a much later period. During the last 40 years several specimens have been seen in the zoölogical gardens of London and Paris, and many have been brought to this country, where they seem to thrive. In its natural, as in its domesticated state, it is gentle, timid, shy, and inoffensive; it is extremely docile in confinement, feeds from the hand, licks the hand which feeds it, and becomes the friend of those who are kind to it. Its natural range appears to be all the wooded parts of eastern, central, and southern Africa, from Sennaar and Abyssinia to the vicinity of the settlements of the Cape of Good Hope, although, like all wild animals, it recedes before the approach of civilization. In domestication it serves no purpose but to gratify curiosity and to promote the study of nature, since it is unfit for draught; and although its flesh is said by hunters to be eatable, it is not suitable for furnishing either meat or milk.

**GIRALDUS CAMBRENSIS.** See BARRY, GERALD.

**GIRARD, Philippe de**, a French inventor, born near Avignon, Feb. 1, 1775, died in Paris, Aug. 26, 1845. In 1806 he exhibited an improvement in lamps, and in the same year made some improvement in the steam engine, producing a rotary motion without a walking beam. His principal invention was a machine for flax spinning, to which subsequently he applied steam, and for which he received the emperor's medal in 1810, and another medal from the national exposition of industry in 1844. He invented several other machines, and for many years was interested in extensive manufactories of linen in Poland and in Austria, as well as in France.

**GIRARD, Stephen**, an American merchant and banker, born near Bordeaux, France, May 24, 1750, died in Philadelphia, Dec. 26, 1831. He was the son of a seaman, and sailed about 1760 as cabin boy to the West Indies and New York. Rising by degrees to be master and part owner of an American coasting vessel, he accumulated in the course of a few years a sum sufficient to establish him in business as a small trader in Philadelphia in 1776. He married about this time the daughter of a ship builder of that city, but the union was unhappy. Mr. Girard applied for a divorce, and his wife ultimately died insane in a public hospital. Mean-

while Girard trafficked with the West Indies with variable success, until his maritime ventures were suspended by the war of the revolution. He then opened a grocery and liquor shop, at first in Philadelphia, and during the British occupation of that city at Mount Holly, where he drove a profitable trade with the American soldiers. In 1780 he resumed his dealings with the West Indies and New Orleans, and some time afterward was in partnership for a few years with his brother John. The connection was dissolved in 1790, Stephen having gained while it lasted about \$80,000. The foundation of his subsequent wealth, however, seems to have been a lease which he took of a range of stores, at a time when rents were much depressed by the war; these he underlet at a large profit. Another source of gain was the negro insurrection in Hayti. Two of his vessels were then in one of the ports of the island, and many of the planters placed their treasures in them for safety, but were afterward cut off with their entire families. About \$50,000 worth of property whose owners could not be found thus remained in Mr. Girard's hands. With a remarkable capacity for business and a habit of strictness in money matters, he rapidly multiplied his wealth, and before long came to be recognized as one of the richest merchants in the city. During the prevalence of the yellow fever in Philadelphia in 1793, '7, and '8, when it raged with a violence never before seen in America, Mr. Girard not only gave money liberally, but performed in person the duties of physician and nurse, undertook the most disagreeable offices in the hospitals, and for two months kept charge of the hospital on Bush hill. In 1812, having purchased the building and a large part of the stock of the old United States bank, he commenced business as a private banker, with a capital of \$1,200,000, which was afterward increased to \$4,000,000. Besides the benefit which this institution proved to the national currency, it enabled Mr. Girard to make heavy loans to the government in times of public embarrassment; and during the war of 1812, when out of a loan of \$5,000,000 proposed by the secretary of the treasury only \$20,000 could be negotiated, he subscribed for the whole amount. He was active in procuring the charter of the second United States bank, of which he became a director. He contributed liberally to all public improvements, and adorned the city of Philadelphia with many handsome buildings. He was frugal and parsimonious, but not avaricious; profuse in his public charities, but stern in exacting the last fraction that was due him. His kindness to the sick was extraordinary, but he never had a friend. His appearance was very plain. He was uneducated; was a free thinker in religion, and an admirer of the school of Voltaire and Rousseau, after whom he was fond of naming his ships. His property at the time of his death

and terminating in a ring of bristly hairs at the summit, surrounding a bare apex. These bristles, according to some naturalists, want only the gluten to cement them into true horns, and embody the animal in the systematic arrangement of the *caticornia*. The giraffe is assimilated to the camel by the length of its neck, by the callosities on its chest and knees, and by its having no false hoofs; to the other ruminants by the structure of its stomach and digestive organs generally, and by its non-possession of the reticulated water bag. To the antelopes it is assimilated by the fact that the coils of its colon are spiral, and that its cæcum is simple. With the solid-horned deer, which shed and renew those appendages annually, it is connected by the assumed fact of its having no gall bladder. In its dental system, the giraffe offers the same formula with the deer, goat, antelope, sheep, and ox, namely: incisors  $\frac{1}{2}$ , canines  $\frac{1}{2}$ , molars  $\frac{1}{2} = \frac{3}{4} = 32$ . The nos-

Giraffe (*Giraffa camelopardalis*).

trils are provided with cutaneous sphincter muscles, and can be shut at will like the eyes. The eyes are beautiful, extremely large, soft and brilliant, and are so placed that the animal can see much of what is passing on all sides and even behind it. Thus it is approached with the greatest difficulty; and if surprised or run down, it can direct the rapid storm of kicks by which it defends itself in the most accurate manner. Its horny hoofs are divided, and it wants the two small lateral toes generally seen in the true ruminants, from which this again distinguishes it. The immense length of its legs and height at the withers, raising the insertion of the neck so far from the ground that the animal can graze on an even surface only with difficulty and by straddling the fore legs wide apart, enables it to feed on what it prefers as food, the delicate and succulent leaves and twigs of the tallest trees, particularly those of a spe-

cies of acacia peculiar to the districts which it inhabits. The peculiar conformation of the tongue, which is furnished with rough papillæ capable of voluntary erection, enables it to gather and collect into little bundles the soft leaves which it likes. Its speed, which is far from contemptible, is shown by the statement of hunters who have pursued it, particularly Capt. Gordon Cumming; all of whom testify that, being timid and wary, and always securing a good start, it is not easily overtaken, except by a swift horse. Its paces are a trot, a pace with both legs moved on the same side, and a regular gallop, by changing from one to the other of which, with no apparent diminution of its speed, it can keep up a considerable rate of going for a long continued time and distance. Le Vaillant, the first well informed modern zoölogist who saw it in a state of nature, asserts that he "knows beyond a doubt that by its kicking it often tires out, discourages, and even beats off the lion." The same fact is shown by Capt. Cumming. Of the adaptation of the giraffe to the country and scenery it inhabits, this observant naturalist and sportsman speaks as follows: "I have often traced a remarkable resemblance between the animal and the general appearance of the loc which it is found. . . . And as the giraffe is invariably met with among venerable trees where innumerable blasted and weather-beaten trunks and stems occur, I have been repeatedly in doubt as to the presence of a troop of tigers until I had recourse to my spy-glass: referring the case to my savage attendants, I have known even their optics to be time mistaking the dilapidated trunks of leopards, and again confounding the leopards with those aged veterans of the forest. This animal when full-grown attains a height of 15, 16, and even 17 feet, formerly believed almost universally that its legs are much longer than they are in fact, taking the legs only from the hip, the hind legs are the longer by much. The great development and height of the withers, to give a proper base to the towering head, have been the source of error. The color of the giraffe is of a deep brown; the neck, back, and the shoulders and thighs are more or less tessellated, dull, rust-colored. The sides the marks are less. The legs are whitish, faintly marked. The tail next to the body is covered with smooth hair; its trunk is very short and coarse, and forms a great knob beyond the tip of the tail. The female is less vivid than that of the male, she is somewhat smaller, and has a protuberance of the frontal bone, and eyes, which by some writers is

rudimental horn, less strongly developed than the male.—The giraffe has been long known to history. It is represented on the painted walls of the sekos of the Meinnonium, discovered and described by Belzoni; and also on the celebrated Prænestine pavement, said to have been constructed by the orders of Sulla, who had served as questor in Numidia. It was exhibited in the *circus maximus* by Julius Caesar, alive, for the first time in Europe, but was afterward a frequent spectacle at the cruel shows of Rome. **GIRARD, Philippe de**, a French inventor, born near Avignon, Feb. 1, 1775, died in Paris, Aug. 26, 1845. In 1806 he exhibited an improvement in lamps, and in the same year made some improvement in the steam engine, producing a rotary motion without a walking beam. His principal invention was a machine for flax spinning, to which subsequently he applied steam, and for which he received the emperor's medal in 1810, and another medal from the national exposition of industry in 1844. He invented several other machines, and for many years was interested in extensive manufactories of linen in Poland and in Austria, as well as in France.

**GIRARD, Stephen**, an American merchant and banker, born near Bordeaux, France, May 24, 1759, died in Philadelphia, Dec. 26, 1831. He was the son of a seaman, and sailed about 1760 as cabin boy to the West Indies and New York. Rising by degrees to be master and part owner of an American coasting vessel, he accumulated in the course of a few years a sum sufficient to establish him in business as a small trader in Philadelphia in 1776. He married about this time the daughter of a ship builder of that city, but the union was unhappy. Mr. Girard applied for a divorce, and his wife ultimately died insane in a public hospital. Mean-

while Girard trafficked with the West Indies with variable success, until his maritime ventures were suspended by the war of the revolution. He then opened a grocery and liquor shop, at first in Philadelphia, and during the British occupation of that city at Mount Holly, where he drove a profitable trade with the American soldiers. In 1780 he resumed his dealings with the West Indies and New Orleans, and some time afterward was in partnership for a few years with his brother John. The connection was dissolved in 1790, Stephen having gained while it lasted about \$30,000. The foundation of his subsequent wealth, however, seems to have been a lease which he took of a range of stores, at a time when rents were much depressed by the war; these he underlet at a large profit. Another source of gain was the negro insurrection in Hayti. Two of his vessels were then in one of the ports of the island, and many of the planters placed their treasures in them for safety, but were afterward cut off with their entire families. About \$50,000 worth of property whose owners could not be found thus remained in Mr. Girard's hands. With a remarkable capacity for business and a habit of strictness in money matters, he rapidly multiplied his wealth, and before long came to be recognized as one of the richest merchants in the city. During the prevalence of the yellow fever in Philadelphia in 1793, '7, and '8, when it raged with a violence never before seen in America, Mr. Girard not only gave money liberally, but performed in person the duties of physician and nurse, undertook the most disagreeable offices in the hospitals, and for two months kept charge of the hospital on Bush hill. In 1812, having purchased the building and a large part of the stock of the old United States bank, he commenced business as a private banker, with a capital of \$1,200,000, which was afterward increased to \$4,000,000. Besides the benefit which this institution proved to the national currency, it enabled Mr. Girard to make heavy loans to the government in times of public embarrassment; and during the war of 1812, when out of a loan of \$5,000,000 proposed by the secretary of the treasury only \$20,000 could be negotiated, he subscribed for the whole amount. He was active in procuring the charter of the second United States bank, of which he became a director. He contributed liberally to all public improvements, and adorned the city of Philadelphia with many handsome buildings. He was frugal and parsimonious, but not avaricious; profuse in his public charities, but stern in exacting the last fraction that was due him. His kindness to the sick was extraordinary, but he never had a friend. His appearance was very plain. He was uneducated; was a free thinker in religion, and an admirer of the school of Voltaire and Rousseau, after whom he was fond of naming his ships. His property at the time of his death

amounted to about \$9,000,000. Comparatively little of it was bequeathed to his relatives. To the Pennsylvania hospital he willed \$30,000; to the Pennsylvania institution for the deaf and dumb, \$20,000; to the orphan asylum of Philadelphia, \$10,000; to the Philadelphia public schools, \$10,000; to the city of Philadelphia, for the distribution of fuel to the poor every winter, \$10,000; to the society for the relief of distressed masters of ships, \$10,000; to the masonic loan, \$20,000; to the city of New Orleans, a large amount of real estate; to the city of Philadelphia, for improvement of its streets, buildings, &c., \$500,000; for the improvement of canal navigation in Pennsylvania, \$300,000. His principal bequest was \$2,000,000, besides the residue of a certain portion of his estate out of which some legacies were to be paid, together with a plot of ground in Philadelphia, for the erection and support of a college for orphans. The most minute directions were given for the construction, size, and materials of the building, which was begun in July, 1833, and opened Jan. 1, 1848. It is surrounded by a stone wall 10 ft. high, enclosing 41 acres laid out in play grounds, grass plats, gardens, &c. The main building is the finest specimen of Grecian architecture in America, and is even said to be the finest of modern times. The outer walls, staircases, floors, and roof are of white marble; the inner walls of brick. It is in the form of a Corinthian temple, surrounded by a portico of 34 columns, each 55 ft. high and 6 ft. in diameter. Its length is 169 ft., its width 111 ft., and its height 97 ft. The entrances are on the N. and S. fronts, each door being 16 ft. wide and 32 ft. high; the E. and W. sides are pierced each by 24 windows. The structure rests on a basement of 11 steps extending around the entire building. A marble statue in the lower vestibule covers the remains of Mr. Girard. There are five other buildings within the enclosure, one of which is used as a laboratory, bakery, wash house, &c. The others stand two on each side of the main building, and are of marble, each two stories high, 125 ft. long, and 52 ft. wide. The cost of the edifices was upward of \$1,930,000. As many poor white male orphans as the endowment can support are admitted between the ages of 6 and 10 years, fed, clothed, and educated, and between the ages of 14 and 18 are bound out to mechanical, agricultural, or commercial occupations. In a recent report the directors say that, the apprenticeship system as it existed in Mr. Girard's time having become obsolete, the execution of that part of the will is now difficult. By a provision of the will of the founder no ecclesiastic, missionary, or minister of any sect whatever, is to hold any connection with the college, or be admitted to the premises even as a visitor; but the officers of the institution are required to instruct the pupils in the purest principles of morality, leaving them to adopt their own

religious opinions. The officers consist of a president, secretary, two professors, five male and five female teachers, a physician, a matron, a steward, and a superintendent of manual labor; and there are about 500 beneficiaries.

**GIRARDIN.** I. *Émile de*, a French journalist, born in Paris, June 22, 1806. The natural son of Count Alexandre de Girardin and Mme. Dupuy, wife of a counsellor, and registered at his birth under the name of *Émile de Lamoignon*, he struggled for years before he gained his right name, and it was not till 1837 that his filiation was definitely established by his parents' public avowal. After being inspector of the fine arts under the Martignac ministry, he established two periodicals: *Le Voleur*, which pilfered from all the other journals, and *La Mode*, a journal of fashion, which enjoyed the patronage of the duchess of Berry. After the revolution of 1830 he established the monthly *Journal des Connaissances utiles*, the price of which was only four francs (less than 80 cents) a year, which soon obtained 120,000 subscribers. Through the agency of this paper he organized a subscription for the establishment of a model farm, known as the *institut agricole de Coëtbo*, and greatly contributed to increase the number of savings banks through the country. He issued other cheap publications in connection with his monthly, as the *Journal des Instituteurs*, at 36 cents a year; a geographical atlas at one cent a map; and the *Almanach de France*, at 10 cents a copy. All these publications were issued as emanating from a *société nationale pour l'émancipation intellectuelle*. He also published the *Journal des Gardes Nationales*, and the *Gastronome*, a culinary paper which was found in every eating house. He was one of the founders of the illustrated weekly *Musée des Familles*. In 1835 he projected the *Panthéon Littéraire*, a series of 100 large vols. 8vo. which were to embrace a mass of letterpress equal to 1,000 ordinary volumes, and to present in a cheap form the standard works of every country. In 1836 he established the *Provençal*, a political daily paper, at a yearly subscription of 40 francs, half the price before paid for such journals. This attempt brought upon him the wrath of nearly all the contemporary journalists of Paris. Both his public and private life were assailed; he was charged with claiming a name which was denied him, with dishonesty in some of his numerous business transactions, and with unscrupulous ambition in his political course. He challenged Armand Carrel, and killed him in the duel, when the clamor against him increased on all sides. But he was undaunted, and secured the full possession of his name and a seat in the chamber of deputies, which was long contested on the ground that he was not a Frenchman, but, as was falsely reported, a native of Switzerland, while he extended the circulation of the *Provençal* so as to place it beyond rivalry. He supported the Molé ministry against the coalition in 1839,

and the ministry of Guizot during most of its duration. On Feb. 24, 1848, he presented himself at the Tuileries and persuaded Louis Philippe to an abdication in favor of his grandson, the count de Paris; but it was too late to save the dynasty. He vigorously supported the new order of things, tried to inspire the French people with confidence in it, and became for a while the most popular journalist in Paris. During a few weeks nearly 150,000 copies of the *Presse* were disposed of daily. His independent politics were deemed dangerous by Gen. Cavaignac, who ordered his arrest after the insurrection of June, and kept him 11 days in strict confinement. On resuming the charge of his journal, Girardin vehemently attacked the rule of the general, and greatly contributed to the election of Louis Napoleon to the presidency, but soon became his opponent, gave his journal a more and more radical and socialistic turn, and after the *coup d'état* of Dec. 2, 1851, was ordered out of France. He afterward returned, but, unable to submit to the restrictions on journalism, sold his share in the *Presse* in 1856 for 800,000 francs. In December, 1862, he again became its chief editor, but he finally abandoned it in 1866, and established *La Liberté*. He attacked the administration vigorously, and in March, 1867, was fined 5,000 francs, and a month later the sale of his journal on the street was prohibited. He still continued to attack the administration, subjecting himself to further prosecution, and he also severely criticised the course of many of the opposition journals. After the formation of the Ollivier ministry (Jan. 2, 1870) he accepted several government commissions. After the proclamation of the republic (Sept. 4) an unpublished decree, bearing date July 27 and countersigned by Émile Ollivier, was found among the papers of the Tuileries, conferring upon Girardin the rank of senator. About the same time he sold *La Liberté* for 1,000,000 francs, and for a time withdrew from journalism. But he soon resumed his pen, and became a vehement supporter of the war against Prussia. During the siege of Paris *La Liberté* was transferred to the country, and he followed it, and on Dec. 24 purchased *Les Centa Jours*, in which he severely criticised the dictatorship of M. Gambetta. During the insurrection of the communists he published a journal called *L'Union Française*, in which he advocated the adoption of a federal system of government. In May, 1872, he purchased the *Journal Officiel*, whose management, however, was retained by its former conductor. The catalogue of his political pamphlets would fill columns. His contributions to the *Presse* from 1836 to 1856 were published in 1858 (12 vols. 8vo), under the title of *Questions de mon temps*. In 1859 he furnished a preface to a work entitled *Les batailles célèbres*, by A. Chagnéraud. His *Le droit de punir* (Paris, 1871), on which he was engaged for ten years, is mainly a supplement to Beccaria's *De delitti e della pena*.

In opposition to *L'Homme-femme*, by Alexandre Dumas fils, he published in 1872 *L'Homme et la femme, l'homme suzerain, la femme vassale*. After the death of his first wife he married (November, 1856) Countess Mina de Tieffenbach, daughter of a former Viennese postmaster, and widow, by morganatic marriage, of Prince Frederick of Nassau. He obtained a divorce from her in 1872. **II. Delphine Gay**, a French authoress, wife of the preceding, born in Aix-la-Chapelle, Jan. 26, 1804, died in Paris, June 29, 1855. She was the daughter of Mme. Sophie Gay, and a poem written by her when scarcely 18 years old gained an extraordinary prize of the French academy. In 1824 she published a collection of *Essais poétiques*. She was accustomed to recite her verses in society, and having extemporized some beautiful lines on the premature death of Gen. Foy in 1825, she was hailed as *la muse de la patrie*, and received from Charles X. a pension of 1,500 francs. On a visit to Italy in 1827 she was elected by acclamation a member of the Tiber academy at Rome, and carried in triumph to the capitol. She married Émile de Girardin in 1831, and produced in 1833 *Napoline*, one of her most charming poems. She had already begun to write novels. *Le lorquon* appeared in 1831, and was succeeded by *M. le marquis de Pontange* in 1835, and *La canne de M. de Balzac* in 1836. From 1836 to 1848 she furnished to the *Presse*, under the *nom de plume* of Vicomte Delaunay, 57 *Lettres parisiennes* on literature, art, and fashion. The only complete edition of these letters was brought out in 1858, with an introduction by Théophile Gautier. In 1839 she wrote a comedy, *L'École des journalistes*, but its representation was prohibited by the government. In 1843 her tragedy *Judith*, designed for Rachel, was performed at the Théâtre Français. Another tragedy, *Cléopâtre* (1847), and the comedy of *Lady Tartuffe* (1853), were also written for that actress. Her comedies, *C'est la faute du mari, ou Les bons mariages font les bonnes femmes* (1851), and *La joie fait peur* (1854), and her vaudeville *Le chapeau d'un horloger* (1854), were highly successful. Her last novels, *Marguerite, ou Deux amours*, and *Il ne faut pas jouer avec la douleur*, appeared in 1853, and a new edition of the former in 1858. An English translation of "The Cross of Berny," the joint production of Mme. de Girardin, Gautier, Sandeau, and Méry, was published in New York in 1873. A complete edition of her works has been published (6 vols. 8vo, Paris, 1860-'61). She was celebrated for beauty and wit.

**GIRARDIN, Jean Pierre Louis**, a French chemist, born in Paris, Nov. 16, 1803. He has popularized chemistry by teaching its application to art, industry, and agriculture, as professor at Rouen from 1838 to 1858, and since at Lille and Clermont. In 1835 he published *Leçons de chimie élémentaire* (2 vols.; 4th revised and illustrated ed., 1860-'62), which has been translated into Russian. His other writings include

manuals of pharmacy, botany, and chemistry, *Mélanges d'agriculture, d'économie rurale et publique, et de sciences physiques appliquées* (2 vols., 1852), and *Des fumiers et autres engrais animaux* (6th revised, enlarged, and illustrated ed., 1864).

**GIRARDIN, Marc**, or, as he signed himself, **Saint-Marc**, a French journalist, born in Paris in February, 1801, died there, April 11, 1873. After completing his classical studies at the college of Henry IV., in 1823 he competed for a professorship in the university, and won the title of *agrégé*, but, on account of his liberal opinions, was not appointed to a chair till 1827. In the latter year the French academy awarded a prize to his *Éloge de Bossuet*, and he became one of the political contributors to the *Journal des Débats*. His connection with this journal continued till 1859, when he joined the staff of the Orleanist *Journal de Paris*, and published *Souvenirs et réflexions politiques d'un journaliste*. In 1828 his *Tableau de la littérature française au 16<sup>e</sup> siècle*, which confirmed his reputation as an elegant, witty, and forcible writer, was rewarded with another academical prize. In 1830 he travelled through northern Germany, and on his return was appointed to succeed M. Guizot as professor of history in the faculty of letters, and named master of requests to the council of state. In 1833 he visited southern Germany as far as Vienna; and in 1834 he published, under the title of *Notices*, the results of his two journeys beyond the Rhine. He was then appointed professor of French poetry at the Sorbonne, and elected to the chamber of deputies. His report on the organization of secondary instruction, presented in 1837, was highly valued. He entered at the same time the council of state and the council of public instruction; as a member of the latter board he greatly contributed to the extension and improvement of the system of historical teaching in the French colleges. In 1844 he was elected to the French academy. In 1848 he was designated minister of public instruction, in the last cabinet attempted under the monarchy, and under the republic and the empire held his position at the council of public instruction and at the Sorbonne. In 1863 he resigned his professorship at the latter institution. He was a frequent contributor to the *Revue des Deux Mondes*, and in 1869 he succeeded Sainte-Beuve as conductor of the *Journal des Savants*. In February, 1871, he was returned to the national assembly for the department of Haute-Vienne. Among his principal works are: *Cours de littérature dramatique, ou de l'usage des passions dans le drame*, an improved reproduction of his lectures; *Essais de littérature et de morale*; and *Souvenirs et voyages*, comprising the notices upon Germany before mentioned.

**GIRARDON, François**, a French sculptor, born in Troyes, March 16, 1628, died in 1715. He was furnished by Chancellor Seguier with the means of studying his art in Paris and Italy.

He was patronized by Colbert, and received orders from the king for groups and statues. Several of the royal palaces and gardens. In 1690 he was appointed general inspector of sculpture, to succeed Lebrun. Some of his most celebrated works were destroyed at the revolution. The most important of those that remain are Richelieu's mansion, a chapel at the Sorbonne, and his groups, "Bath of Apollo" and the "Rape of Proserpine" in the Versailles garden.

**GIRAUD, Charles Joseph Barthélemy**, a French jurist, born at Pernes, Vaucluse, Jan. 1, 1802. He studied at Aix, where he became professor of administrative science and member of the academy. In 1842 he became inspector general of the law schools in France, and member of the French academy. Subsequently of the board of education; he was vice rector of the academy of Paris in 1848. He was twice minister of public instruction in 1851 and member of the legislative council, from which he retired in 1852, in consequence of the confiscation of the property of the Orleans family. He has filled the chair of Roman law in the faculty of Paris, and succeeded Laferrière in 1861 as inspector general of the judiciary. His principal works are: *Histoire du droit français au moyen âge* (2 vols., Paris, 1846); *Le droit d'Utrecht* (1847; translated into German and Spanish); *Les tables de Salpensa et de Bithynie* relating to the bronze tables found in the locality (2d ed., revised and enlarged, 1861); and *Études nouvelles sur Grégoire VII.* in the *Revue des Deux Mondes* of Dec. 15, 1873, et seq.

**GIRGENTI, L.** A province of Sicily, on the S. W. coast; area, 1,491 sq. m.; pop., 289,018. Its surface is mountainous, with numerous valleys, which are exuberant and yield corn, wine, and oil in abundance. There is good pasture. The productions are gypsum, bitumen, and especially sulphur. (See *Girgentum*), capital of the province, on the coast, and 58 m. S. E. of Palermo; pop., 18,000. It is situated on a hill formed here by the junction of the *Hypsus* and *San Bi* (anc. *Acron*). Mount Camicus, over 10,000 ft. high, the acropolis of ancient Agrigento, with its four walls and gates, is called the count of its picturesque situation. In the fine English garden. But, except the street, there are only steep slopes, yet the houses, wretched as they are, have fine balconies, and the inhabitants many beggars (though fewer are dressed in a blue velvet, as the women were). The cathedral, of Norman architecture, owes its foundation in 1181 to the king. It contains many chapels, in which are

relics, an ancient sarcophagus with sculptures supposed to represent the story of Phædra and Hippolytus, and a celebrated *porta voce*, from whence a conversation, though carried on in the lowest voice, may be overheard at a distance of about 300 feet. There are many other churches, and formerly, when the population included a large number of priests, there were many convents and nunneries. The college of Girgenti is among the most important in Sicily, and the Lucchesiana library contains about 100,000 volumes. The palazzo Buonadonna is the principal of the palaces, and the most remarkable classical vestige is the temple of Zeus Polieus, now the church of Santa Maria de' Greci. Subterranean chambers filled with stalactites are supposed to have been quarries whence the stone was supplied for the buildings of the ancient city. There are immense granaries hewn in the rock near the port, which is protected by a mole, built of fragments from the temple of Zeus Olympius. Sulphur is the principal article of trade, and the other chief exports are grain and olive oil. While the *piscina* or water reservoir was one of the most remarkable public works of the ancient city (see AGRIGENTUM), Girgenti suffers from the utter want of a supply of water. The excavations of the ancient sepulchres have discovered painted vases more varied and larger than any others found in Sicily, and almost equalling those of Apulia and Campania. The spring or fountain near the city, to which Pliny refers as yielding petroleum or mineral oil, still exists; and the mud volcano described by Solinus, and to which the Saracens gave its present name of Maccalubba, continues to be one of the many curious sights in the vicinity of Girgenti.

**GIRODET-TRIOSON, Anne Louis** (GIRODET DE COURSSY), a French painter, born in Montargis in 1767, died in Paris, Dec. 9, 1824. He was a pupil of David, and obtained the great prize, which enabled him to go to Rome in 1789. During a residence of five years in Italy he sent to Paris the "Sleeping Endymion" and "Hippocrates declining the Gifts of Artaxerxes." On his return to Paris in 1795, he painted portraits of Chateaubriand and Hortense, and several large pictures, as "Danaë," "The Seasons" for the king of Spain, "Fingal, Ossian, and their Descendants welcoming to their Aerial Palace the Manes of French Heroes," and in 1806 his most esteemed work, "A Scene of the Deluge," which created a great popular sensation and bore away the prize from David's "Sabines." In 1808 he completed his "Funeral of Atala," in 1810 his "Revolt at Cairo," and in 1819 his "Pygmalion and Galatea." His literary remains were published in 1829, in 2 vols.

**GIROUDE**, a S. W. department of France, formerly a part of the province of Guienne, bordering on the bay of Biscay and the departments of Charente-Inférieure, Dordogne, Lot-et-Garonne, and Landes; area, 3,759 sq. m.; pop. in 1872, 705,119. The surface is almost

entirely level, the W. portion being a vast sandy, arid flat, collectively called the Landes. The chief rivers are the Garonne and Dordogne, which unite to form the Gironde, the Isle, Dronne, Dropt, and Leyre. The climate is temperate, and, except in the Landes, generally healthy. The principal productions are wheat, rye, millet, maize, hemp, fruits, wine, cork, charcoal, turpentine, pitch, and timber. Wine is the staple product, 55,000,000 gallons being made annually. The most renowned Bordeaux wines are produced in the Gironde. Building stone, salt, and chalk are the principal mineral products. The manufactures include calicoes, muslin, earthenware, paper, leather, glass, tobacco, brandy, beer, vinegar, salt, chemicals, and cordage. Ship building is extensively carried on in Bordeaux. Railways connect Bordeaux with Paris, Bayonne, &c. The department is divided into the arrondissements of Bordeaux, Blaye, Lesparre, Libourne, Bazas, and La Réole. Capital, Bordeaux.

**GIRONDISTS** (Fr. *Girondins*), a French political party, which played a conspicuous part in the legislative assembly and the convention. They derived their name from the deputies of the department of Gironde, whom they acknowledged as their leaders. Vergniaud, Gensonné, Guadet, Brissot (from whom they were sometimes styled Brissotins), Condorcet, Ducos, Boyer-Fonfrède, Louvet, Pétion, Valazé, Buzot, Barbaroux, Isnard, Lanjuinais, Carra, and Rabaut Saint-Étienne were the most prominent of their members. They enthusiastically promoted the proclamation of the republic (September, 1792), but strongly opposed the ultra-revolutionary party, called the Montagnards; and although eloquence, talent, and virtue were mostly on their side, they succumbed to the violent assaults of their opponents after having been driven by the current to vote in part and reluctantly for the death of Louis XVI. The Montagnards charged them with plotting against the unity of the republic and aiming at a federal organization of the country. After a most stormy debate on May 31, 1793, 22 of them were arrested on June 2, incarcerated at the Conciergerie, and on Oct. 31 executed. Mme. Roland, their inspirer, and her husband followed them soon after (November), the former dying by the guillotine, the latter by his own hand. The other Girondist leaders escaped from Paris, and, after vainly attempting to revolutionize several departments, were almost all either taken prisoners and beheaded, or committed suicide.—See Lamartine, *Histoire des Girondins* (8 vols., Paris, 1847).

**GISLASON, Conrad**, an Icelandic philologist and lexicographer, born July 3, 1808. He is the son of a popular poet, and studied at the university of Copenhagen, where he became professor of the Norse languages. Besides numerous editions of old Icelandic writings and commentaries on early Scandinavian poetry and philology, he has published a critical manual of the rudiments of the ancient Icelandic

according to the earliest records (1846); a Danish-Icelandic dictionary, the first ever published (1851); and an unfinished work on early Norse inflections (1858).

**GISORS**, a town of Normandy, France, in the department of Eure, in a fertile plain on the banks of the Epte, 33 m. E. S. E. of Rouen; pop. in 1866, 3,753. It is surrounded by gardens and beautiful promenades formed upon the remains of its ancient ramparts. Its castle, most of which is still standing, was very strong, and one of the chief fortresses of Normandy. It was built about the 11th century, but the donjon, an enclosed octagonal structure crowning a high artificial mound, was constructed in the 12th century by Henry II. of England. Under one of the towers is a dungeon, the walls of which are covered with carvings executed with a nail by some unknown prisoner. The parish church is filled with grotesque sculptures. The choir is said to have been built by Blanche of Castile.

**GITSCHIN**, a town of Bohemia, on the Cydlina, 50 m. N. E. of Prague; pop. in 1869, 6,570. It is walled, and has three gates and four suburbs. The parish church is built after the model of that of Santiago de Compostela in Spain. The former Jesuit college is used as barracks. It was a collection of wretched hovels before Wallenstein made it the capital of the duchy of Friedland in 1627, and the seat of a magnificent palace in 1630. The storming of Gitschin by the Prussians, June 29, 1866, ended the campaign in the territory of the Iser; and the overwhelming defeat of the Austrians here paved the way for the junction of the first and second Prussian armies and for the victory of Sadowa (July 3).

**GIULIO ROMANO**, an Italian painter and architect, whose family name was PIRPI, born in Rome in 1492, died in Mantua in 1546. He was the most distinguished pupil of Raphael, whom he assisted in many of his paintings, and who made him his chief heir and appointed him to complete his unfinished works. After the death of his master, Leo X. and Clement VII. employed him, together with Gian Penni, to finish the history of Constantine in the Vatican; and he executed several works for the public edifices at Rome, was also employed there as architect, and painted his celebrated picture of the "Stoning of St. Stephen" for the church of San Stefano at Genoa. He was afterward invited to Mantua, and engaged both as architect and painter on the palazzo del Tè. The "Defeat of the Titans," in one of the halls of the palace, is one of the best examples of his style. He worked with his pupils on many other edifices at Mantua, and just before his death was appointed to succeed Sansovino as architect of St. Peter's.

**GIURGEVO**, a town and river port of Roumania, in Wallachia, on the left bank of the Danube, opposite Rustchuk, and 34 m. S. by W. of Bucharest; pop. about 15,000. Its citadel, the only one of its fortifications remain-

ing, stands on an island in the Danube Slobodze, and is connected with the town by a bridge. Next to Braila it is the most important port on the Wallachian bank of the Danube, and carries on a considerable trade with Germany and Hungary. Giurgevo has been in almost all the Turkish wars on the Danube, from the 15th century down to the war of 1853.

**GIUDICI, Paolo Emiliani**, an Italian writer, born at Mussomeli, Sicily, June 15, 1812, moved to Florence in 1840, and published *Storia della letteratura italiana* (2d ed., 1853). He was professor at Pisa from 1849 to 1852, and of the royal academy of fine arts in Florence from 1859 to 1862, of which he became president. In 1867 he was returned to the Italian parliament as a deputy for Sicily. His *Storia della letteratura italiana* (8 vols., 1858-'4), a work with new documentary evidence, and a translation of Macaulay's "History of England," was followed in 1856 by his *Storia della letteratura italiana*; and he has long been known upon a history of the Florentine democracy.

**GIUSTI, Giuseppe**, an Italian poet, born at Monsummano, in Tuscany, in May, 1804, died in Florence, March 31, 1850. He was an advocate at the university of Pisa, entered the law office of the future king of Sardinia, Victor Emmanuel, at Capoguardia. But on account of the constitution and disapprobation of the king, he abandoned the practice of law. He was in full sympathy with the liberal cause, and other opponents of the government in Italy, and his poem *Il 1848* on the death of the emperor Francis I. attracted considerable attention. As a writer of moderate liberalism he was twice elected to the Tuscan chamber of deputies after spending the summer of 1848 at the springs of Viareggio, he ended his life in the Florentine palace of his devoted wife. Though published writings had acquired a wide popularity over Italy, when the appearance of a new edition in 1845 impelled him to have his works republished in his own name. But the political and complete edition was published at his death, under the title of *Opere inedite* (Florence, 1852).

**GIUSTINIANI, Agostino**, an Italian prelate and philologist, born at Livorno, died at sea in 1586. Educated by the Dominicans of Florence, he became a professor of that order in 1488, studied languages, taught in several colleges, and published his *Prælectiones* (Venice), in Hebrew and Latin. He was appointed abbot of the monastery of Corsica, was present at the Lateran council, and solicited a promotion to the retirement offered at Ivrea, continuing his

went to Paris at the invitation of Francis I., who appointed him his chaplain, and under whose auspices he published shortly afterward his Hebrew-Latin edition of the book of Job. After filling for five years the chair of Hebrew in the university of Paris, he returned to Genoa, then torn by factions, was seriously wounded while trying to quell a riot, and thence proceeded to Nebbio, where he spent the remainder of his life in his episcopal duties. The principal work of Giustiniani is his *Psalterium Hebraicum, Graecum, Arabicum, Chaldaicum, cum tribus Latinis Interpretationibus et Glossis* (fol., Genoa, 1516). In a note to one of the psalms is the first printed biographical sketch of Christopher Columbus. He also left in manuscript a polyglot New Testament.

**GIVET**, a town of France, in the department of Ardennes, on the Meuse, 22 m. N. by E. of Mézières, on the Belgian frontier; pop. in 1866, 5,801. It is a fortified place of considerable importance, its principal defence being the citadel of Charlemont on an adjacent height. The town consists of Le Grand Givet, or Givet-Notre-Dame, on the right bank, and Le Petit Givet, or Givet-St.-Hilaire, with the fortress Charlemont, on the left bank of the Meuse, which are connected by a bridge built by Napoleon I., and all of which are within the lines of fortification. Givet has manufactures of wire, pencils, and leather, for the last of which it is celebrated.

**GIVORS**, a town of France, in the department of Rhône, on the Gier and the Rhône, 13 m. S. of Lyons; pop. in 1866, 9,957. It has extensive glassworks and tanneries, brick yards, foundries, and silk factories. The place is important as a shipping point for coal. Near it the Givors-Gier canal, begun in 1765 and completed in 1781, joins the Rhône, which is thus connected with the Loire. In the vicinity are the ruins of the castle of St. Gerald and the convent of St. Ferréol.

**GIZEH**, *Ghizeh*, or *Jizeh*, a town of Egypt, capital of a province of the same name, on the W. bank of the Nile, 3 m. S. W. of Cairo. It was once a large city, but is now a petty village surrounded by heaps of ruins. The khedive has a palace there. About 5 m. from the village stand the three great pyramids called those of Cheops, Cephren, and Mycerinus. At Gizeh are ovens in which eggs have been hatched artificially ever since the days of the Pharaohs. (See PYRAMIDS.)

**GIZZARD**. See COMPARATIVE ANATOMY, vol. v., p. 181.

**GLACIAL THEORY**. See DILUVIUM, and GLACIER.

**GLACIER** Fr. *glacier*, from *glace*, ice), a vast body of ice, filling some alpine valley, down which it slowly moves, the outlet of the snows which accumulate in the elevated portions of the mountain group. Glaciers may be found in all countries where extensive tracts lie above the snow line. In such localities the snows are ever accumulating, and the temperature

not rising sufficiently for any considerable proportion to be melted and flow down, they fill the spaces between the summits. By the pressure exerted by these vast collections the yielding material is forced through whatever opening is presented for its passage, and the great valleys leading to the base of the mountains are packed full of ice, which results from the snow being solidified by pressure, or by its own melting and freezing again. This, solid as it appears, is steadily though imperceptibly urged onward, conforming to all the irregularities of its channel, split sometimes by immovable ledges of rock, which stand like islands in its course, yet closing again below them with no trace of the fissure. These bodies of ice extend down the valleys till they reach a region where the temperature is sufficiently elevated to melt away the supplies as they arrive. Though these have gradually diminished toward the lower extremity of the glacier, so that this has flattened away somewhat like a wedge, and has also become narrower, the termination is frequently abrupt and even inaccessible. It presents an apparently stationary wall of ice, which, though seen to be constantly wasting, may yet by observations continued several days be found steadily advancing from the mountain. During the summer currents of water formed from superficial thaws flow over its surface, at least in the daytime, and fall in cascades into the numerous chasms, which extend across the glacier. They continue their course, hollowing out through the lower layers of the ice arched channels, which at the lower end appear like dark caverns extending far up into the icy mass. In high polar latitudes, where the line of perpetual snow comes down to the sea level, the phenomena of glaciers are displayed upon the grandest scale. Thus they were seen in lat. 79°-80° by Dr. Kane in 1855, spreading over the western coast of Greenland, and sloping so gently toward the water that the effect of an inclined plane was perceived only by looking far into the interior toward the east. In this long range the angle of the slope was from 7° to 15°. Yet the whole icy crust of this portion of the continent was always advancing and stretching itself out into the western bay, where masses of it were constantly detached and floated off as icebergs. From this glacier to the southern extremity of Greenland, more than 1,200 m., Dr. Kane imagined a deep unbroken sea of ice might extend along the central portions nearly the whole length of the continent.—The study of the geology of California had enabled Prof. Whitney to point out the traces of immense glaciers which at a time geologically recent had existed in the mountains of the Sierra Nevada. The alteration of the climate and the diminution of the rainfall consequent upon comparatively recent geological changes, have however caused the disappearance of the greater part of these, and it was not till 1870 that Mr. Clarence King discovered actual glaciers on

the N. side of the extinct volcano of Mt. Shasta in northern California. From the summit, 14,440 ft. above the sea, according to him, we look down on three considerable glaciers. One of these has a breadth of three or four miles, and sends branches four or five miles down the cañons. Its thickness is estimated in places to be 1,800 ft. or more, and its surface presents great crevasses, some of them 2,000 ft. long, and 30 or 40 ft. wide. Mr. S. F. Emmons has also found glaciers on Mt. Rainier or Tachoma in Washington territory, and Mr. Arnold Hague on Mt. Hood in Oregon; while more recently Mr. John Muir has succeeded in finding small glaciers much further southward in the sierras near the Yosemite valley on Mts. Lyell, McClure, and Hoffmann. They have the structure and movement of true glaciers, but the largest is not more than a mile in length, and they vary in breadth from half a mile to a few feet.—The phenomenon of glaciers reaching the sea and becoming icebergs was noticed by Darwin in the gulf of Peñas, Patagonia. In northern Europe, it has been observed in Norway, in lat. 67° N., and in America on the W. coast of Greenland. Upon the Himalaya mountains the glaciers appear from the accounts of modern travellers to be exhibited in masses of stupendous height, as well as of vast extent. In the "Himalayan Journals" of Dr. Joseph Hooker, those of the eastern portion of the range, in the territories of Sikkim and Nepaul, are described in detail, and mention is made of one which presents a vertical height of 14,000 ft., the source of which is the great Kinchinjunga, whose summit reaches the elevation of 28,000 ft. above the sea. Other gigantic glaciers in the central Himalaya are described by Dr. Thomas Thomson ("Western Himalaya and Tibet"), and by Col. Madden and Capt. Richard Strachey, in the "Asiatic Researches," vol. xiv. Iceland, Spitzbergen, the Caucasus, and the Altai have their glaciers, which have been described by travellers; but no regions have afforded such convenient opportunities for studying them in detail as the Alps of Switzerland, Savoy, Piedmont, and Tyrol. Here, in the heart of Europe, they are found covering in detached portions an aggregate area computed at 1,484 sq. m. Between Mont Blanc and the borders of Tyrol 400 are reckoned, of which the greater number are between 10 and 20 m. long, and from 1 to 2½ m. broad. Their vertical thickness in many places is rated at 600 ft.; their range is from above the snow line, which is from 7,500 to 8,000 ft. above the sea, down to the level of 3,500 to 3,000 ft. Lateral ravines have their glaciers, which join as branches the ice currents of the great valleys. This interesting region was studied by De Saussure in the latter portion of the last century, and his views were published in his *Voyages dans les Alpes* (1796). Charpentier is distinguished among later explorers as the able advocate of the theory explaining the motion of the glaciers, afterward sustained by Agassiz in his

*Études sur les glaciers* (1840); and Prof. D. Forbes of Edinburgh published in 1841 "Travels in the Alps," &c., with observations on the phenomena of glaciers made in 1838 to them repeated in ten different summers, in which he crossed the principal chain 27 times by 23 different passes. Many other distinguished naturalists have aided not only to develop the true nature of glaciers, but to apply their phenomena to the explanation of past changes upon the earth's surface.—Spread over the broad valleys, glaciers appear immovable. The snow disappears from their face in summer, and thousands of streams are then produced which waste their material; but with the return of winter the covering of snow is renewed, and no change may be perceived in the great mass except such as can be referred to these superficial causes. But by comparative observations made at different times, it is perceived that the great mass itself moves. The constant renewal of the waste at the lower extremity, already referred to, is evidence of this. Objects on the surface, however, may be continually moving down, even when their position on the ice itself is not changed. At the high precipices at the sides masses of stone fall along the edges of the glacier, but it is obvious that they do not rest in an immovable talus; for where one mass opens into another the piles of stones at the fork do not terminate as they join at the junction, but are continued in a long series of varieties of stone far down the glacier. Other branches come in, each forming a mound, till sometimes as many as a dozen ridges are thus produced. These ridges are in contact below, and thus be reduced to a level, and even be blended with the general surface. In some form, however, they continue to the foot of the glacier; ridges of boulder-shaped stones are seen, which lie in front of the glacier, and are sometimes repeated in nearly parallel ridges along a sea beach, each ridge being the limit of some previous glacier. Great ridges of sand and stone, or borders, mark the limits reached by the glacier at former times; but these marks are all removed when the glacier again sweeps far up the mountains. At certain periods are observed ridges of sand and stone before the advancing glacier, and these are in a new and larger moraine at a distance from the mountains. It is evident from these facts that the habitable valleys are sometimes invaded by the terrible ice. Imperceptibly but irresistibly it is advancing upon the farms and cottages. In warm summer weather the ice is obvious in its dissolution, yet the process is slow and diminish. The green grass is seen before it; and the groves are withered by its icy touch, before the soil is covered by its ruthless ploughshare. When,

advance, the glacier recedes to its former bounds, the surface it covered is found to be changed into a dismal waste of loose stones.—The gathering and distribution of these materials by action of glaciers have been subjects of special interest, from the resemblance in most of the phenomena exhibited to those connected with the distribution of the geological formation known as the drift. The loose rocks are worn into the rounded forms of boulders, and are similarly striated and grooved upon their surface, and sometimes polished. The rocks upon and against which the glaciers have pressed are found, wherever exposed to view, to be ground smooth and deeply marked with lines corresponding in direction with the course of the glacier at the spot. It is upon these resemblances, and others connected with minor details of the two classes of phenomena, that the glacial theory of Venetz and Charpentier, so fully elaborated by Agassiz, is based, accounting for the distribution of geological formations like the drift. The transporting power of glaciers was recognized by Prof. Playfair of Edinburgh as far back as the year 1816, and the occurrence of the enormous boulders on the Jura was attributed by him to glaciers, whose track he supposed lay at one time across the valley of Switzerland and the lake of Geneva, which now separate the Jura from the opposite summits of Mont Blanc. It is on these summits, at the distance of from 70 to 80 m., that are found the ledges of granite and other rocks, which are recognized as identical with the great boulders scattered over the surface of the Jura limestone. (See *Dictionnaire*.)—The quantity of stony material, and the enormous size of the masses of rock carried along by glaciers, are little appreciated, even by many who have seen the loads apparently resting quietly on their surface. Sometimes the ice is almost concealed by the accumulated piles of stone. These do not sink into the ice, except as they occasionally fall into the chasms, and even then they are sometimes brought again to the surface by the action of the forces which keep most of them there. As the rock protects the ice beneath it from the action of the sun, which has its melting effect around, the rock is thus gradually lifted upon a pedestal of ice, at the same time that the whole is slowly moving down to a lower level. When the pedestal at last gives way, the rock slips down and the process is repeated. When once in the ice, the superficial melting may bring it again to the surface. The size of the fragments is often immense. Prof. Forbes saw one in the valley which must have been brought down by the glacier, which was nearly 100 ft. long, and from 40 to 50 high; and at the foot of the glacier of Swartzburg in the valley of Saas was another estimated to contain 244,000 cubic feet, requiring an average diameter of nearly 62 ft.—The rate of progress of glaciers, dependent upon various conditions, is no more uniform than that of rivers. It can in no case

be correctly estimated except by observations extending over many years. On the glacier of Aar M. Hugi erected a hut in 1827 at the foot of a fixed and well known rock. In 1836 the hut was 2,200 ft. from the rock, and in 1840 this distance had doubled. In the first period its progress had been 250 ft. per annum, and in the second 550. Forbes in 1842 found the remains of a ladder, which, it is believed, was the one left by De Saussure in 1788 at a point 16,500 ft. further up the glacier; if so, its yearly progress had been 375 ft. This movement extends through valleys in which the surface of the glacier appears to lie almost on a dead level. It is made manifest day by day by a row of stakes set up in a straight line across the glacier, and ranging with fixed points on the land at the sides. These are after a time observed to stand upon a semicircular line, the stakes near the middle moving faster than those near the margin. The importance of correctly estimating the rate of movement at short intervals and in different parts of a glacier, in order to determine the nature of the motion, appears to have been first appreciated by Agassiz in 1841, and by Forbes, who was engaged about the same time in his explorations. Agassiz discovered that the central portion moved faster than the marginal, and he was the first to correct the erroneous views into which he had been led by others on this point, from the fact of the great cracks generally lying in curved lines with the convexity directed up the course of the glacier. (*Système glaciaire*, by Agassiz, Guyot, and Desor, p. 462.) The upward convexity of the fissures is accounted for by the fact that, if the central portion moves fastest, the lines of greatest tension are downward and toward the middle, and the ice gives way at right angles to these lines. Forbes, by careful instrumental observations in 1842, detected the rate of movement in periods of 24 hours, and was able even to notice that which took place in an hour and a half. He proved the faster rate of the central portions, and also that the portions of the glacier near the surface moved faster than those near the bottom. The motion he found was greatest on the slopes of greatest descent; in warm weather more rapid than in cold; yet always continuous, and not exhibited in the manner of jerks. Such facts are opposed to the theory of De Saussure, that the glaciers move by slipping along upon their bed, the motion being made more easy by the buoyant property of the water flowing beneath them, and the propelling force being that of gravitation. Moreover, the ice, without being broken up, was observed not to be interrupted in its movement by the contracted passages through which it was sometimes forced to pass, nor by solid hills of rock, which lay like islands in its path. The theory maintained by Charpentier, and supported by Agassiz in his *Études sur les glaciers*, was that the glacier slid upon its bed, not necessarily in large bodies pushed on by gravitation, but that different

portions were impelled by different degrees of force, arising from the expansion of the water congealing in all the fissures and capillary tubes of the ice into which it found its way. The facts developed by Forbes—that the motion was greatest in the warm summer weather, when the temperature did not descend below the freezing point, and that it did not cease when the ice was no longer liquefied in the cold of winter—demanded some new explanation. With the other phenomena they were regarded by him as sufficient to establish the fact that ice in large bodies is not a brittle solid, but that it possesses, particularly when saturated with water, so much plasticity, that with time it can yield to a stupendous and steadily exerted force, and move somewhat like a body of viscous pitch or lava, which, while it appears brittle when suddenly struck, can yet mould itself in the mass to the surface upon which it rests. By this theory, which was generally received even by those who first opposed it, all the difficulties attending the explanation of the movement disappear. It was confirmed by a simple experiment made by Mr. Christie, secretary to the royal society. He filled with water a 10-inch hollow shell of iron, the shell itself being besides  $1\frac{1}{2}$  in. thick, and exposed this to severe cold. As the water expanded in freezing, a cylinder of ice was pushed up through the fuse hole, and it continued to increase in length as the water continued to freeze. As the outer portions of the water must have been first converted into ice, it is plain that it was this so-called solid material which was forced through the narrow aperture and made to assume the form of a cylinder of its diameter. But the peculiar nature of this quality of mobility belonging to ice has been more perfectly explained, together with some of the other phenomena of glaciers, by the researches of Tyndall and Huxley, an account of which is published in the "Philosophical Magazine," vol. xv. (4th series), 1858. The property of particles of ice when exposed to higher temperatures than the freezing point to adhere, and under pressure to unite in one mass, was observed by Faraday, and was afterward made the subject of various experiments by Tyndall and Huxley. They found that compact transparent ice might be crushed to fragments, and these be made by a hydraulic press to assume in a few seconds the shape of any mould, recovering in their new form perfect solidity and transparency. A straight bar of ice was bent into a semicircular form by using a succession of four moulds of gradually increasing curvature. As the prism conformed itself to these, cracks were produced, and crackling sounds were emitted, reminding one of those which are so often noticed among the phenomena of glaciers. By reference to this before unobserved property of ice the movement and unbroken continuity of glaciers and their branches are now explained.—The glaciers from their very source present a series of changes of

structure, which have been critic and traced, and in some i ted and explained by experi scale with other materials. known by the French term *névé* is of dry and granular snow, which ex miles, sometimes broken by and at others presenting no surface such as are common to low, no streams, crevices, moraines. The snow lies in strata, which re depth, each representing the acc single year, the lowest the most approaching the blue color of ice. The move onward to form the glac as they pass into this, their more and more the character of But a remarkable and peculiar fe veined or laminated structure, real parent, which it assumes. This is the walls of the fissures, and is also upon the surface of the glacier it this has been wasted by rain. This of transparent blue ice alternate of white porous ice, and standing vertical position the edges of the foject a little above those of the l more readily melt, and thus a rib ance is produced. The direction onæ is across the fissures, and as ob Tyndall and Huxley these are pr right angles to the direction of gre sion. They find an analogy between nation of the ice and the slaty clea clays and slates, both which they pressure causing the development of planes in lines approximately at ri to the direction of pressure. Hence liquity of the lamination to the glacier as the lines extend from the ward the middle and down its co the deviation directly across the gla right angles with this and parallel axis, as the form of its bed or produce a pressure in the one case longitudinally and in the other laterally line of the glacier. By submitting materials, as wax, to pressure, and ob laminated structure these a vestigators were led to this phenomenon as developed in others, as Prof. Forbes, describe as produced merely by lines of air bubbles in the blue ice itself, according to the observation of P Thompson, of partial liquefaction i pressure; and Prof. William T tempts to prove "that the first sure not equal in all directions ou snow ought to be, according to the convert it into a stri d ss of alternately clear and ice. lar to the direction of But the complete explanation will require experimental researches which have not yet been made.—

most striking feature in the appearance of glaciers, which attention was first directed by Forbes, is the distribution of what he called the dirt streaks, discolored streaks seen upon the surface, which he supposed were connected with the veined structure, appearing where this is more energetically developed than elsewhere, caused by the collection of sand and dirt in the decomposed portions of the softer laminae. These are arranged in curves, the continuity of which is turned down the glacier, and are frequently so obscure that they are distinguished only by looking down upon them from some elevation. Tyndall and Huxley describe them as spread out upon the smooth ice in the ice cascades, and caused a similar symmetrical arrangement of dark-colored sand distributed upon the surface of a current of mud, which they made to flow from a reservoir down an inclined trough, through a narrow channel, which spread out below over a widened area.—Various other phenomena connected with the structure and motion of glaciers are discussed in the treatises on this subject already referred to. Besides the works mentioned, see "Norway and its Glaciers" (1860), and "On the Theory of Glaciers" (1869), by James D. Forbes; *Die Gletscher der Jetztzeit*, by A. Mousson (1854); *Neue Untersuchungen über die physikalische Geographie und die Geologie der Alpen*, by the brothers Magintweit (1854); "The Glaciers of the Alps," by John Tyndall (1860); "The Old Glaciers of North Wales and Switzerland," by A. C. Ramsay (1860); and "The Land of Glaciation," by Dr. Isaac I. Hayes (1871).

**GLADBACH**, the name of two towns of Prussia, in the province of the Rhine. **I. Mönchengladbach**, in the district and 16 m. W. by S. of the city of Düsseldorf; pop. in 1871, 26,326 (against 4,090 in 1852). It is one of the chief seats of the industry of Rhenish Prussia, having numerous manufactories of cotton, linen, silk goods, tobacco, machines, and wire, and a number of bleaching grounds. Formerly there was here a celebrated Benedictine abbey, which was founded in 972 by Archbishop Bruno of Cologne. **II. Bergisch-Gladbach**, in the district and 8 m. N. E. of the city of Cologne; in 1871, 6,195. It contains manufactories of paper and percussion caps. In its vicinity is the village of Bensberg, with a castle built in 1610, and now converted by the Prussian government into a military academy.

**GLADIATORS** (Lat. *gladius*, a sword), in Roman antiquity, men who fought with each other or with wild animals at the public games, for the entertainment of spectators. They were originally captives, slaves, or condemned criminals; but under the republic free-born citizens, and under the empire knights, senators, and even women, fought in the arena. Those who were malefactors were divided into two classes: those condemned *ad gladium*, to be killed within a year, and *ad ludum*, who were discharged if they survived three

years. Professional gladiators were trained in schools at Rome, Capua, and Ravenna, by overseers (*lanistæ*), who either purchased and maintained them to let them out for public exhibitions, or only trained them for their owners. Clodius and Milo employed gladiators as a political force in their struggle; Cæsar had 5,000 of them at Capua, who were not overlooked by Pompey. They were taught the postures to be assumed in falling and in dying, and such food was chosen as would thicken their blood in order to give the spectators a more leisurely view of their death. The public combat between gladiators began with weapons of wood, which were soon exchanged for deadly arms. Usually they were matched by pairs. According to their arms or modes of fighting, gladiators were divided into numerous classes. The *andabata* fought blindfolded, the *catervarii* in troops, the *essedarii* in chariots, the *equites* on horseback, the *hoplomachi* in full armor, the *laqueatores* with the lasso, the *mirmillones* with the weapons of the ancient Gauls, the *Samnites* with those of the people of Samnium, the *Thracæ* with a dagger and round buckler. The *retiarii* were lightly equipped, and fought by throwing a net lasso-fashion over the head of their antagonist, and then despatching him with a three-pointed lance or trident. If a combatant was vanquished, but not killed, his fate depended on the people, who turned their thumbs down if they wished him to be spared. A man who had once been a gladiator was always regarded as disgraced, and, if a knight, could not resume his rank. Gladiatorial contests were first exhibited at Rome in 264 B. C., as an entertainment at funerals, and they continued till the reign of Honorius (A. D. 404), when Telemachus, a Christian monk, rushed between two contending gladiators at Rome, and by his self-sacrifice occasioned the decree for their abolition. The passion for them had risen to its height under the emperors. Titus ordained a combat of 100 days, and Trajan one of 123 days, in which 10,000 gladiators fought, and 11,000 fierce animals were killed. Rome was imperilled about 72 B. C. by a rebellion of gladiators. (See SPARTACUS.)

**GLADIOLUS** (Lat. *gladius*, a sword), a genus of ornamental plants of the *iridaceæ* or iris family. A flattened solid bulb or corm sends up a stem bearing several long, sword-shaped, strongly nerved leaves, and terminating in a spike of large and usually showy flowers, which are somewhat irregular from the difference in the size of the petals, and more or less two-lipped. Sword lily and corn flag are names sometimes applied to these plants, but they are generally called by their botanical name *gladiolus*. There are both hardy and tender species. The hardy ones are planted in autumn at the same time with hyacinths, tulips, &c.; the principal ones cultivated are *G. communis*, from Europe, which has been longer in the gardens than any other, and bears a few rose-colored, sometimes white flowers, and *G. Byzantinus*,

from the Levant, which has larger and more showy purple flowers. Among the tender species which are grown in pots in winter, or planted in the open ground in spring, are *G. cardinalis*, *G. blandus*, and *G. psittacinus*, from the Cape of Good Hope. The most popular and brilliant of these plants are hybrids from these and probably others; they originated in the garden of the duke of Ardenburg, a noted amateur of Ghent; and as their characters are permanent and they are fertile among themselves, these hybrids have received the garden name of *gladiolus Gandavensis*. In size, beauty of form, and variety of coloring of the flower, these hybrids far excel any of the species, and they are constantly improving in these respects; new seedlings of merit are each year raised both in Europe and America, and the catalogues now offer named varieties in hundreds. The colors range from pure white through rose to crimson, scarlet, and violet;

Common Gladiolus.

some have yellow as the predominating color, and there are various intermediate shades of salmon, chamois, and others; besides self-colored flowers, there are those variously striped, stained, and shaded in the most brilliant and pleasing combinations. The cultivation is very easy, as they will grow in any light, rich garden soil; the bulbs are planted in spring, and, if a succession of flowers is desired, at intervals from March until May; they are set 2 or 3 in. deep, and 10 to 12 in. apart each way, and need no other care than to be kept clear of weeds, and to have such stalks as need it tied to sticks. A very effective plan is to plant the bulbs where the flowers will be seen against a background of evergreens; they may also be introduced among rhododendrons, azaleas, and other spring-flowering shrubs. In autumn when the stalks are dead the bulbs are taken up, labelled, wrapped in papers, and kept in a dry place, where they will not freeze, until spring.

The number of bulbs annually produced from one to several, according to the size. At the base of the bulbs there will be found numerous bulblets, the size of a pea; smaller; planted the next spring, the flowering bulbs in two years. New varieties are obtained from the seed; flowers the third or fourth year.

**GLADSTONE, William Ewart**, an English statesman, born in Liverpool, Dec. 29, 1809, the fourth son of Sir John Gladstone, a merchant, who relinquished a large fortune at Glasgow about 1785, and retired to Liverpool, where he acquired a large fortune in the West India trade, and was created a baronet in 1846. The son was sent to Eton, where he gave full promise of the success which marked his course at Oxford, and graduated at Christchurch in 1831 in the first class, the highest honor, and attained, and became a fellow of All Souls. After travelling for a short period he entered parliament in December, 1832, as member for Newark, a nomination borough in the county of Newcastle, which he represented till 1846. In December, 1834, he was appointed by Sir Robert Peel a member of the treasury, and in 1835 under-secretary for colonial affairs, which office he held for two months, when the ministry was thrown. He continued a useful and well known brilliant member of the cabinet led by Sir Robert Peel until his return to power in 1841, when he was made a member of the privy council, and served as vice president of the board of trade and master of the mint. In 1845 he explained and defended in parliament the commercial policy of the government, and his vision of the British tariff in 1846 was entirely his work. He was a contributor to the "Quarterly Review," a literary and ecclesiastical journal, published in 1838, in which he maintained extreme views, and which was severely criticised by Macaulay in the "Edinburgh Review." In May, 1848, he succeeded Lord John Russell as president of the board of trade, but in 1845, he resigned his position on the measure for the repeal of the Corn Laws, which was a principle to the opinion he had formed. His work on church and state. In 1845, Sir Robert Peel resigned the office of failure of Lord John Russell's ministry, he was recalled to the cabinet, Mr. Gladstone was made secretary for the colonies. In the free trade question announced by Sir Robert Peel, Mr. Gladstone fully concurred, and was willing to remain under obligation to the duke of Newcastle, he resigned his seat in parliament in 1847, and was chosen to represent

Oxford, and one of his first speeches in parliament was in favor of the bill for the removal of the disabilities of the Jews, which he had introduced in 1841. His speech against the foreign policy of Lord Palmerston in the Donetsko debates was generally regarded as one of the most admirable pieces of English eloquence of recent times. In the ministerial crisis of 1852 he was invited by Lord Derby to enter his cabinet, but declined, and on the overthrow of that minister in December of the same year accepted the office of chancellor of the exchequer under the earl of Aberdeen. While holding this office he introduced in 1853 a celebrated budget in a remarkable series of addresses which were pronounced by Lord John Russell "to contain the ablest expositions of the true principles of finance ever delivered by an English statesman." On the resignation of Lord Aberdeen in February, 1855, and the elevation of Lord Palmerston to the premiership, Mr. Gladstone retained his office of chancellor of the exchequer; but he soon resigned, together with the other Peelite members of the government, in consequence of Lord Palmerston's refusing to oppose a motion of inquiry into the conduct of the Crimean war, which was considered indirectly to convey a censure on the duke of Newcastle and Mr. Sidney Herbert.

On the overthrow of Lord Palmerston's government and the second accession of Lord Derby to power in 1858, Mr. Gladstone again declined the pressing overtures of that nobleman, but in November accepted an appointment as third high commissioner extraordinary to the Ionian islands. In 1859, on Lord Palmerston's return to office, Mr. Gladstone again became chancellor of the exchequer. He was chiefly instrumental in procuring the repeal of the Corn Law, and the ratification of the commercial treaty between England and France, negotiated by Mr. Cobden and M. Chevalier. In this time Mr. Gladstone has been classed as an advanced liberal. He was chiefly instrumental in procuring the repeal of the Corn Law, and the ratification of the commercial treaty between England and France, negotiated by Mr. Cobden and M. Chevalier. In this time Mr. Gladstone has been classed as an advanced liberal.

He also during the succeeding years exhibited a theoretical knowledge and a practical skill in the management of the national finances that excited the admiration of all Europe. At the general election of 1865 he was rejected by the university of Oxford, but was returned for South Lancashire. After the death of Lord Palmerston the same year, Mr. Gladstone became the member of the house of commons. He procured the adoption of the measures recommended by the ministry for the suppression of the Fenian disturbances in Ireland, but a reform bill introduced by him on behalf of the ministry was defeated, and he and his colleagues resigned. They were succeeded by one formed by Lord Derby and Mr. Disraeli, July 6, 1866. In the early part of the session of 1868 Mr. Gladstone introduced a series of resolutions in favor of disestablishment and disendowment of the Irish church. Soon after a bill for effecting the same object was passed by the commons, but rejected by the peers. In the general election

of that year Mr. Gladstone was defeated as a candidate for Southwest Lancashire after an exciting contest, but was returned by a large majority by the borough of Greenwich. Mr. Disraeli's ministry resigned in December, and Mr. Gladstone succeeded him as premier. The Irish church bill was passed at the session of 1869, the Irish land act in 1870, and the purchase of commissions in the army was abolished in 1871 by the exercise of the royal prerogative. He also procured the abolition of confiscation in English penal law. During the war between France and Germany the English government, under the lead of Mr. Gladstone, maintained a complete neutrality, and in order to avoid all complications with the great powers of the continent reluctantly consented to the abrogation of those provisions of the treaty of 1856 with Russia which established the neutrality of the Black sea. Under his administration the treaty of Washington, by which the matters in dispute between the United States and Great Britain were settled, was negotiated and carried into effect. At the session of 1873 Mr. Gladstone introduced an elaborate bill for the reform of university education in Ireland, the main object of which was the establishment of a system which should be acceptable to both Protestants and Catholics. The discussion in the house of commons made it clear that the bill satisfied neither, and it was defeated. Mr. Gladstone and his colleagues immediately resigned. The queen called upon Mr. Disraeli to form a new ministry, but after some days he announced to the house that he was unable, and if not unable unwilling, to do so, and declared that he did not regard the defeat of the university bill as exhibiting such a want of confidence in the general conduct of the government as required the resignation of the ministry. Mr. Gladstone and his colleagues accordingly returned to their posts; but repeated defeats of the ministry followed, and on Jan. 24, 1874, Gladstone unexpectedly issued an address announcing the dissolution of parliament, assigning as a reason for the step that the government felt its power was ebbing. He promised a diminution of local taxation and the abolition of the income tax. The succeeding elections for a new parliament resulted in the return of 351 conservatives and 302 liberals, a conservative majority of 49, against a liberal majority of 112 in that of 1868. Mr. Gladstone himself was returned from Greenwich by a vote of 5,968, against 6,386 in 1868. On Feb. 17 he resigned, and on the following day Mr. Disraeli accepted the premiership. Mr. Gladstone's published works are: "The State in its Relations with the Church" (2 vols., 1838); "Church Principles Considered" (1840); "Studies on Homer and the Homeric Age" (3 vols., Oxford, 1858); "Essays on *Ecce Homo*," and a pamphlet on the Irish church question, entitled "A Chapter of Autobiography" (1868); and "Juventus Mundi: the Gods and Men of the Heroic Age" (1869). He has

supervised a translation of Farini's *Stato Romano* (4 vols., London, 1859). In 1851 he published a "Letter to Lord Aberdeen" on the cruelties inflicted on the political prisoners confined in the dungeons of Naples, which produced a universal and very deep impression. His statue, by Adams Acton, was unveiled in Liverpool on Sept. 11, 1870.

**GLADWIN**, an E. county of Michigan, intersected by Titibiwassee river; area, 570 sq. m.; returned without population in 1870. Its surface is uneven, and its soil consists of a sandy loam.

**GLAGOLITIC**, one of the two ancient Slovenic, or less correctly Slavonic, forms of writing. The name is derived from the fourth letter, *glagol*, equivalent to our hard *g*; it is also known as the Bukvitza, from *bukra*, letter, or from the names of the second and third letters, *buk* and *ride*, or *b* and *v*. Its formation is attributed by some to St. Jerome, and by others to Methodius, the apostle of Pannonia and Great Moravia (about 860). The shape of the 32 letters (of which 27 are also numeral signs) is very grotesque and protean, little resembling the Greek. The Glagolitza was used in Illyria, Dalmatia, and Bulgaria. The other form of Slovenic writing is the Kyrilitza, contrived by Cyril, the reputed brother of Methodius, many letters of which are like the Coptic, because they imitate the Greek forms. This consisted originally of 40 letters, and is still in use among the eastern Slavs and the Roumanians. The Russian *azbuka* or *bukvar* (alphabet) is a slight modification of the latter. These systems have been much extolled by some authors; but, though representing all sounds of the languages, they are imperfect, inasmuch as they contain single signs for complex sounds, such as *tz*, *tch*, *shtch*, *ye*, *ya*, *yu*. The nations that employ these graphic systems belong mostly to the Greek church; while the Catholic Slavs (Poles, Bohemians, Slovaks, Lusatians, &c.) make use of the Latin or the so-called German letters, with some modifications. The most remarkable works in Glagolitic writing are: *Glagolita Cloziana*, by Count Paris Cloz of Trent in the 11th century, edited by Kopitar (Vienna, 1836); *Codex Assemanicus, continens Lectiones Evangelicas*, *Bibliotheca Vaticana*, in A. Mai's *Scriptorum Veterum Nova Collectio*; and *Codex continens Psalmos, cum Expositione Sancti Athanasii*, &c., at Bologna. All these are in the Bulgarian idiom; *Breriarium* (edited by Brozich, Venice, 1561) is in Servian.

**GLAIRE**, Jean Baptiste, a French theologian and orientalist, born in Bordeaux, April 1, 1798. He completed his theological studies at St. Sulpice seminary, Paris, and afterward studied the oriental languages. Taking holy orders in 1822, he taught Hebrew in his seminary, and in 1825 he succeeded Chaunac de Lanza as professor of Hebrew at the Sorbonne. In 1841 he was made dean of the faculty of theology, and in 1843 was transferred to the chair of exegesis. In 1840 he

became a canon of the metropolis of Paris, and in 1851 vicar general. His most important works are *con Manuale Hebraicum et Chaldaicum*, new ed., considerably enlarged and revised (1843); *Principes de grammaire hébraïque et chaldaïque* (1832; new eds., 1836 and 1843); *La sainte Bible en Latin et en Français*, with notes, explanations, &c. (3 vols., 1836); *Torath Mosché, Le Pentateuque*, with translation and notes, of which parts only have been published (Exodus (2 vols. 8vo, 1836-'71), *historique et critique aux livres de l'Ancien et du Nouveau Testament* (6 vols. 8vo, 1843); an abridgment of which appeared in 1843, vol. 8vo.); *Manuel de l'hébreu*, a grammar, a chrestomathy or collection of texts, and a lexicon (1856); *Concordance du Coran*; *Principes de grammaire arabe* (1861); *La Bible selon la Vulgate*, with notes (1863); and *Dictionnaire des sciences ecclésiastiques* (2 vols., 1864).

**GLAIS-BIZOIN**, Alexandre, a French politician, born at Quintin, department of Côte d'Or, March 9, 1800. He acquired prominence as an opposition member of the chamber of Louis Philippe. After the revolution of 1848 he was elected to the constituent assembly, but owing to his hostility to the government he soon withdrew from political life. He was, however, he again became conspicuous as a representative by his incessant interruptions of the debates, and by his invariably opposing the measures of the government. In the elections of 1869 he was elected in his native department, but was defeated. In 1870, he became a member of the national assembly, and subsequently represented it with Tours. The charges of embezzlement against him by the press he strenuously denied, declaring he had sacrificed his private fortune to public service. He was elected to the commune in May, and after his arrest by the authorities of Versaille he was immediately released. He is the author of several plays, and in 1868 became director of the republican weekly journal, *La Tribune*.

**GLAISHER**, James, a British aeronaut, born about 1800. He early became famous as an aeronaut, and was a meteorologist. In one of his ascents, on Sept. 5, 1862, he reached an altitude of 10,000 ft. (See *AERONAUTICS*.) He was a fellow of the royal society in 1865, and in 1865 Admiral Fitzroy as director of the meteorological department of the navy, and was one of the members of the geological society, and, except for a short time, which he was its president, till 1873, when he resigned. His "Travels in the Air" (London, 1862) is a popular account of balloon voyages.

**GANSHIRE**, a S. county of Wales, on Carmarthenshire, Brecknock-shire, the Severn, and Bristol; area, 855 sq. m.; pop. in 1871, 100,000. The northern portion is mountainous, the southern is level and fertile. The crops are wheat, barley, oats, beans, peas, and turnips. The horned cattle are of superior quality, and in the mountainous parts numbers of sheep and ponies. Glamorganshire is famous for its iron mines. In the neighborhood of Llanidloes the iron works are on a gigantic scale, within a small circuit are more than 100 ironworks, some of which have 6,000

Vast quantities of coal and iron ore are annually exported from Cardiff. This county has also some woollen manufactories, numerous canals and railways. The principal towns are the Rhymney, the Taff, and the Neath. The chief towns are Cardiff, the capital, Llanidloes, Swansea, and Neath.

*Lat. gland*, an acorn, in anatomy, the name of a variety of organs whose function is to elaborate the various products which come from the blood, to perform certain functions connected with absorption and assimilation, to assist in preparing and maintaining fluid in a normal condition. The first class of glands the liver and the lungs are examples, of the second the

salivary and lymphatic glands, and of the third the spleen. The true secreting glands vary in form, size, and structure, but are all distinguished by the fact that they are furnished with special reference to the secretion of the nucleated and epithelial cells, or cavities which enter into their structure, their products are poured forth on the outer surface of the body, or into a vessel which communicates externally, or into a duct which effect the separation of the secretions from the blood are in the relation of epithelium cells to the secretions of the skin or mucous membrane. The greater part of their function is to form the greater part of their secretions. These cells generally minister to the secretion by absorbing from the blood its watery and saline ingredients, and afterward excrete in the requisite form, and by generating at the same time the organic ingredient by their own power, thus producing a secreted matter of a composition from the blood from which it was derived. The great glands provided with ducts may be divided into three groups, according to the character of the cell containing tubes are 1, the simple tubular glands, like those of the stomach and intestines, in which the cells are more depressions in the membrane, or elongated vesicles lined with cells, 2, the aggregated or compound glands, in which a number of simple glands are united into lobules, and these are surrounded by loose areolar tissue, and 3, the tubular glands, pro-

state, and lachrymal glands, and also the liver; 3, the convoluted tubular glands, as the perspiratory and sebaceous glands ending in dilatations, cul-de-sacs, or loops. In all a large extent of secreting surface is packed in a small compass; while one end of the gland and duct opens on a free surface, the

Ultimate Glandular Follicle.  
a. Membrane of the follicle. b. Layer of epithelium lining the follicle, seen in profile. c. Surface of epithelium cells, lining the whole interior of the follicle.

opposite end is closed, and has no direct communication with blood vessels or other canals. The glandular organs have been divided into two classes, according as their product is excrementitious and to be cast off, or to be used

Mucous Gland, from the Cavity of the Mouth.

within the system; the former are called more properly excretory glands, and include the kidneys, and those which supply the cutaneous and pulmonary transpiration and the peculiar fecal matters of the lower part of the intestinal canal; the true secretory glands are the gastric, salivary, mammary, sebaceous, mucous, lachrymal, Brunner's, and the pancreas. The kidneys, liver, mammary glands (secreting respectively urine, bile, and milk), and the pancreas are described under their proper titles; the salivary and gastric glands are noticed under Digestion; the sebaceous, ceruminous, odoriferous, and sudoriparous glands (secreting the oily, waxy, odorous, and perspiratory matters of the surface), are treated in the article Skin; the follicles of Lieberkühn (in the small intestine), Brunner's glands in the duodenum, and the solitary glands most numerous in the

surrounded with a vascular plexus, and filled with an albuminous fluid containing fat granules and nucleated cells. The opinion that these glands serve for the higher organization of the blood materials is supported by the fact that they are especially large and active during fetal life and childhood, when the most abundant supply of nutrient fluids is necessary. They are not essential to life in the adult; the thymus entirely disappears, the thyroid may be completely disorganized, and the spleen be removed (as has been often done in animals), without fatal consequences; the supra-renal capsules seem to be connected with the production of pigment, and their morbid condition or atrophy is connected with the peculiar disease known as "bronzed skin."—The last group includes the absorbent glands, the patches of Peyer, the mesenteric, and the lymphatic glands. The lacteals and the fluid they convey have been described under **ABSORPTION** and **CHYLE**. Peyer's glands, most numerous toward the ileo-cæcal valve, are intimately con-

dered. The pus of one will p and farcy always terminates i arrested. Farcy commences like swellings of the lymph glands, called farcy buds, which form fistulous ulcers, discl But it must not be unde usually commences in farcy: monly primary. In glander farcy the blood is deficient and otherwise unfit to nourish respiration is weak, and the usually the bowels are relaxed to be produced by continuous overcrowding in filthy and poorly ventilated stables, and other causes induce a depraved state of the British cavalry horses are affected with glanders from the Crimea in 1854. G divided into three stages. It is difficult to distinguish the disease. There is a continuous ser-

have his symptoms much aggravated; while if cold is the cause, the symptoms will be improved, although the horse may be weakened. The enlargement of a submaxillary gland and its adhesion to the bone is usual. If the disease is glanders, the discharge increases, and becomes foul and offensive, and it is said peculiar. This is the second stage. In the third stage the nasal membrane attains a dull leaden color, the lips and eyelids swell, parts of the face may become gangrenous, and the animal may die in a few days with a putrid fever, or he may die more slowly, the disease spreading to the lungs and other parts of the body, producing unhealthy abscesses, emaciation, and hectic. According to Youatt, the distinctive symptoms are the continuous discharge and the adherence of the enlarged submaxillary gland. Sometimes the disease may last for years, if the animal is well fed and cared for. The form known as farcy is also not generally so rapidly fatal, and may sometimes be arrested and prevented from passing into glanders. The treatment in both forms consists in good feeding, tonics, disinfectants, and detergent washes and applications, particularly carbolic acid and creosote. The administration of iodine is generally beneficial in chronic cases.—When the disease is communicated to man, it is usually considered fatal. A small portion of the diseased matter from the nostril of the horse is sufficient to communicate it if it falls upon the mucous membrane, or upon an abraded surface of the skin. The disease may appear as either glanders or farcy, and either may be acute or chronic. Acute glanders begins with the symptoms of putrid poisoning, such as lowness of spirits, wandering pains, fever, furred tongue, great thirst, profuse nocturnal perspiration, great pain in the head, back, and limbs, and tightness of the chest. In a few days the symptoms increase in severity, with rigors and delirium; the perspiration becomes sour and offensive, and diarrhoea sets in. Diffused abscesses appear, commencing in red swellings, about the joints, especially the knees and elbows. The tongue becomes dry and brown, the throat ulcerated, attended by a low malignant fever. In 10 or 12 days from the commencement a dusky shining swelling appears on the face, extending over the scalp and closing the eyes. An offensive yellowish discharge, streaked with blood, flows from the nostrils, and a crop of hard pustules about the size of a pea appears on the face, and spreads over the neck and body; fresh abscesses form and suppurate, accompanied with delirium and tremors, and death ensues. The chronic form proceeds more slowly, attended with discharge from the nostrils, swelling of the nose and eyes, and emaciation, with profuse perspiration and abscesses near the joints. The distinctions between acute and chronic farcy are not very clear, although in the former the lymphatics leading from the point receiving the contagion become violently inflamed the sooner. The treatment of the

human subject should be conducted upon the same general principles as that of the horse.

**GLANVILLE**, or **Glanville**, **Ranulf de**, chief justiciary of England in the reign of Henry II., died in 1190. He was of Norman descent, signalized his valor under Henry II. in repelling the invasion of England by William of Scotland, accompanied Richard I. on the crusade, and perished at the siege of Acre. To him is ascribed the *Tractatus de Legibus Consuetudinis Regni Anglie, Tempore Regis Henrici Secundi*, first published in London in 1554. Some of the manuscripts say only that it was written in his time, without ascribing it to him. The best edition is that by John Wilmot (1780); English translation by John Beames (1812).

**GLANVILL, Joseph**, an English divine and philosopher, born in Plymouth in 1636, died in Bath, Nov. 4, 1680. He was educated at Oxford, became a priest, and was made rector of the abbey church, Bath, in 1666. He became chaplain in ordinary to the king, and in 1678 was appointed a prebendary of Worcester cathedral. He is distinguished as an opponent of Aristotelianism, as a believer in witchcraft, and as the first writer in England who presented philosophical skepticism in a systematic form. His first work, entitled "The Vanity of Dogmatizing," was published in London in 1661, and an enlarged edition of it appeared in 1665, under the title of "Scepsis Scientifica, or Confessed Ignorance the Way to Science," with a dedication to the newly founded royal society, which body at once elected him a fellow. He made another attack on the ancient philosophy in his "Plus Ultra, or the Progress and Advancement of Knowledge since the Days of Aristotle" (1668), in which he exalted Bacon and Boyle and the inductive method. Notwithstanding his skepticism, he believed in sorcery and witchcraft, and wrote "Philosophical Considerations concerning the Existence of Sorcerers and Sorcery" (1666), the convictions expressed in which are repeated in his *Sulducianus Triumphans*, published posthumously (1681), with an account of his life and writings by Dr. Henry More. Among his other works are *Lux Orientalis* (1662), in which he treats of the pre-existence of souls, following the views of Henry More; "Essays on several Important Subjects in Philosophy and Religion" (1676); "Essay on Preaching" (1678); and sermons edited by Dr. Horneck (1681).

**GLARUS**, or **Glaris**. **I.** One of the smallest of the Swiss cantons, bounded N. and E. by St. Gall, S. by Grisons, and W. by Uri and Schwytz; area, 267 sq. m.; pop. in 1870, 35,150, of whom 28,238 were Protestants and 6,888 Roman Catholics. Mountain chains occupy almost its entire surface; the principal one extends from the Hausstock to the Scheibe, and has an average height of 8,000 ft., but there are many separate peaks of much greater elevation. The Dodi or Todi, nearly 12,000 ft. high, in the S. W. corner, is the loftiest mountain in eastern Switzerland. The principal valley, the Lin-

thal, extends N. and S. and forms the basin of the Linth, which, after receiving nearly all the other rivers of Glarus, discharges into Wallenstadt lake. There are many other lakes, mostly small, but remarkable for their romantic scenery. The Stackelbergerbod, a sulphurous alkaline spring at the foot of the Braunwaldberg, is much frequented. Not more than one fifth of the canton is susceptible of tillage. The most fertile land lies in the valley of the Linth, where grain and fruit, particularly cherries, are cultivated with success. Large herds of cattle, sheep, and goats are pastured on the mountains. With the exception of marble, slate, and gypsum, there are no minerals of much importance. Small quantities of coal are found, and there are ancient mines, now almost exhausted, of silver, copper, and iron. The principal kinds of timber are pine, beech, ash, maple, and chestnut. The most important manufacture is *Schabziegerkäse*. (See CHEESE.) The other manufactures comprise cotton, woollen, linen, and silk goods, prints, muslins, writing slates, and many articles in wood. An active trade is carried on with Germany and Italy, transportation being effected through a number of mountain passes, and by means of two canals which connect the Linth with the lakes of Wallenstadt and Zürich. Glarus enjoys a singularly democratic form of government, the supreme power residing in a general assembly of all the males 18 years of age and upward, who meet annually to elect magistrates and accept or reject the laws proposed by the executive council of 80 members. Taxation is very light, there are few crimes, and education is almost universal. The military contingent is about 1,300 men. The chief towns are Glarus, Mollis, and Schwanden.—The name Glarus is sup-

posed to be a corruption of St. Hilar whose honor a church was built in this town about 490 by an Irish monk called Friar, the founder of the convent of Seckingen on the Rhine. The upper part of the valley has been the property of this convent, while the lower was dependent upon the nunnery of Schilt. It was afterward subject to bailiffs nominated by the house of Hapsburg, to escape whose tyranny the inhabitants joined the Swiss confederation in 1352, and in 1360 secured their independence by the famous battle of Näfels. Zwingli was curate of Glarus from 1506 to 1516. The introduction of Protestantism gave rise to many disturbances. Glarus town, capital of the canton, situated in a beautiful Alpine valley at the foot of Mt. Säntis and Schilt, on the left bank of the Linth, is here crossed by two bridges, 33 m. S. of Zürich; pop. in 1870, 5,516. It contains a Gothic church, used by both Catholics and Protestants, a free school for 700 children, a new government house, an old town hall, a bank, and a printing office. The streets are crooked and narrow, and the houses are artistically painted. Cottons, woollens, and hardware are the principal manufactures. In 1861 the town was almost wholly destroyed by fire, which caused a loss of 8,000,000 francs. The environs are very picturesque.

**GLASCOCK**, an E. county of Georgia, bounded S. W. by Ogeechee river and a line to Rocky Comfort creek; area, 225 sq. m.; pop. in 1870, 2,736, of whom 819 were colored. The surface is level and the soil moderately fertile. The chief productions in 1870 were 8,000 bushels of wheat, 52,886 of Indian corn, 1,000 of sweet potatoes, 5,405 of peas and beans, and 1,394 bales of cotton. Capital, Gib
